# Chapter 1

# Introduction

CVODES [34] is part of a software family called SUNDIALS: SUite of Nonlinear and DIfferential/ALgebraic equation Solvers [20]. This suite consists of CVODE, ARKODE, KINSOL and IDA, and variants of these with sensitivity analysis capabilities. CVODES is a solver for stiff and nonstiff initial value problems (IVPs) for systems of ordinary differential equation (ODEs). In addition to solving stiff and nonstiff ODE systems, CVODES has sensitivity analysis capabilities, using either the forward or the adjoint methods.

### 1.1 Historical Background

FORTRAN solvers for ODE initial value problems are widespread and heavily used. Two solvers that have been written at LLNL in the past are VODE [3] and VODPK [5]. VODE is a general purpose solver that includes methods for both stiff and nonstiff systems, and in the stiff case uses direct methods (full or banded) for the solution of the linear systems that arise at each implicit step. Externally, VODE is very similar to the well known solver LSODE [30]. VODPK is a variant of VODE that uses a preconditioned Krylov (iterative) method, namely GMRES, for the solution of the linear systems. VODPK is a powerful tool for large stiff systems because it combines established methods for stiff integration, nonlinear iteration, and Krylov (linear) iteration with a problem-specific treatment of the dominant source of stiffness, in the form of the user-supplied preconditioner matrix [4]. The capabilities of both VODE and VODPK have been combined in the C-language package CVODE [10].

At present, CVODE may utilize a variety of Krylov methods provided in SUNDIALS that can be used in conjuction with Newton iteration: these include the GMRES (Generalized Minimal RESidual) [33], FGMRES (Flexible Generalized Minimum RESidual) [32], Bi-CGStab (Bi-Conjugate Gradient Stabilized) [36], TFQMR (Transpose-Free Quasi-Minimal Residual) [14], and PCG (Preconditioned Conjugate Gradient) [15] linear iterative methods. As Krylov methods, these require almost no matrix storage for solving the Newton equations as compared to direct methods. However, the algorithms allow for a user-supplied preconditioner matrix, and for most problems preconditioning is essential for an efficient solution. For very large stiff ODE systems, the Krylov methods are preferable over direct linear solver methods, and are often the only feasible choice. Among the Krylov methods in SUNDIALS, we recommend GMRES as the best overall choice. However, users are encouraged to compare all options, especially if encountering convergence failures with GMRES. Bi-CGStab and TFQMR have an advantage in storage requirements, in that the number of workspace vectors they require is fixed, while that number for GMRES depends on the desired Krylov subspace size. FGMRES has an advantage in that it is designed to support preconditioners that vary between iterations (e.g. iterative methods). PCG exhibits rapid convergence and minimal workspace vectors, but only works for symmetric linear systems.

In the process of translating the VODE and VODPK algorithms into C, the overall CVODE organization has been changed considerably. One key feature of the CVODE organization is that the linear system solvers comprise a layer of code modules that is separated from the integration algorithm, allowing for easy modification and expansion of the linear solver array. A second key feature is a

2 Introduction

separate module devoted to vector operations; this facilitated the extension to multiprosessor environments with minimal impacts on the rest of the solver, resulting in PVODE [7], the parallel variant of CVODE.

CVODES is written with a functionality that is a superset of that of the pair CVODE/PVODE. Sensitivity analysis capabilities, both forward and adjoint, have been added to the main integrator. Enabling forward sensitivity computations in CVODES will result in the code integrating the so-called sensitivity equations simultaneously with the original IVP, yielding both the solution and its sensitivity with respect to parameters in the model. Adjoint sensitivity analysis, most useful when the gradients of relatively few functionals of the solution with respect to many parameters are sought, involves integration of the original IVP forward in time followed by the integration of the so-called adjoint equations backward in time. CVODES provides the infrastructure needed to integrate any final-condition ODE dependent on the solution of the original IVP (in particular the adjoint system).

Development of CVODES was concurrent with a redesign of the vector operations module across the SUNDIALS suite. The key feature of the NVECTOR module is that it is written in terms of abstract vector operations with the actual vector functions attached by a particular implementation (such as serial or parallel) of NVECTOR. This allows writing the SUNDIALS solvers in a manner independent of the actual NVECTOR implementation (which can be user-supplied), as well as allowing more than one NVECTOR module to be linked into an executable file. SUNDIALS (and thus CVODES) is supplied with serial, MPI-parallel, and both openMP and Pthreads thread-parallel NVECTOR implementations.

There were several motivations for choosing the C language for CVODE, and later for CVODES. First, a general movement away from FORTRAN and toward C in scientific computing was apparent. Second, the pointer, structure, and dynamic memory allocation features in C are extremely useful in software of this complexity. Finally, we prefer C over C++ for CVODES because of the wider availability of C compilers, the potentially greater efficiency of C, and the greater ease of interfacing the solver to applications written in extended FORTRAN.

## 1.2 Changes from previous versions

#### Changes in v3.2.0

Support for optional inequality constraints on individual components of the solution vector has been added to CVODE and CVODES. See Chapter 2 and the description of CVodeSetConstraints in §4.5.6.1 for more details. Use of CVodeSetConstraints requires the NVECTOR operations N\_MinQuotient, N\_VConstrMask, and N\_VCompare that were not previously required by CVODE and CVODES.

Fixed a thread-safety issue when using ajdoint sensitivity analysis.

Fixed a problem with setting sunindextype which would occur with some compilers (e.g. arm-clang) that did not define \_\_STDC\_VERSION\_\_.

Added hybrid MPI/CUDA and MPI/RAJA vectors to allow use of more than one MPI rank when using a GPU system. The vectors assume one GPU device per MPI rank.

Changed the name of the RAJA NVECTOR library to libsundials\_nveccudaraja.lib from libsundials\_nvecraja.lib to better reflect that we only support CUDA as a backend for RAJA currently.

Several changes were made to the build system:

- CMake 3.1.3 is now the minimum required CMake version.
- Deprecate the behavior of the SUNDIALS\_INDEX\_TYPE CMake option and added the SUNDIALS\_INDEX\_SIZE CMake option to select the sunindextype integer size.
- The native CMake FindMPI module is now used to locate an MPI installation.

- If MPI is enabled and MPI compiler wrappers are not set, the build system will check if CMAKE\_<language>\_COMPILER can compile MPI programs before trying to locate and use an MPI installation.
- The previous options for setting MPI compiler wrappers and the executable for running MPI programs have been have been depreated. The new options that align with those used in native CMake FindMPI module are MPI\_C\_COMPILER, MPI\_CXX\_COMPILER, MPI\_Fortran\_COMPILER, and MPIEXEC\_EXECUTABLE.
- When a Fortran name-mangling scheme is needed (e.g., LAPACK\_ENABLE is ON) the build system will infer the scheme from the Fortran compiler. If a Fortran compiler is not available or the inferred or default scheme needs to be overridden, the advanced options SUNDIALS\_F77\_FUNC\_CASE and SUNDIALS\_F77\_FUNC\_UNDERSCORES can be used to manually set the name-mangling scheme and bypass trying to infer the scheme.
- Parts of the main CMakeLists.txt file were moved to new files in the src and example directories to make the CMake configuration file structure more modular.

#### Changes in v3.1.2

The changes in this minor release include the following:

- Updated the minimum required version of CMake to 2.8.12 and enabled using rpath by default to locate shared libraries on OSX.
- Fixed Windows specific problem where sunindextype was not correctly defined when using 64-bit integers for the SUNDIALS index type. On Windows sunindextype is now defined as the MSVC basic type \_\_int64.
- Added sparse SUNMatrix "Reallocate" routine to allow specification of the nonzero storage.
- Updated the KLU SUNLinearSolver module to set constants for the two reinitialization types, and fixed a bug in the full reinitialization approach where the sparse SUNMatrix pointer would go out of scope on some architectures.
- Updated the "ScaleAdd" and "ScaleAddl" implementations in the sparse SUNMatrix module to more optimally handle the case where the target matrix contained sufficient storage for the sum, but had the wrong sparsity pattern. The sum now occurs in-place, by performing the sum backwards in the existing storage. However, it is still more efficient if the user-supplied Jacobian routine allocates storage for the sum  $I + \gamma J$  manually (with zero entries if needed).
- Added new example, cvRoberts\_FSA\_dns\_Switch.c, which demonstrates switching on/off forward sensitivity computations. This example came from the usage notes page of the SUNDIALS website.
- The misnamed function CVSpilsSetJacTimesSetupFnBS has been deprecated and replaced by CVSpilsSetJacTimesBS. The deprecated function CVSpilsSetJacTimesSetupFnBS will be removed in the next major release.
- Changed the LICENSE install path to instdir/include/sundials.

#### Changes in v3.1.1

The changes in this minor release include the following:

• Fixed a minor bug in the cvSLdet routine, where a return was missing in the error check for three inconsistent roots.

4 Introduction

• Fixed a potential memory leak in the SPGMR and SPFGMR linear solvers: if "Initialize" was called multiple times then the solver memory was reallocated (without being freed).

- Updated KLU SUNLinearSolver module to use a typedef for the precision-specific solve function to be used (to avoid compiler warnings).
- Added missing typecasts for some (void\*) pointers (again, to avoid compiler warnings).
- Bugfix in sunmatrix\_sparse.c where we had used int instead of sunindextype in one location.
- Added missing #include <stdio.h> in NVECTOR and SUNMATRIX header files.
- Fixed an indexing bug in the CUDA NVECTOR implementation of N\_VWrmsNormMask and revised the RAJA NVECTOR implementation of N\_VWrmsNormMask to work with mask arrays using values other than zero or one. Replaced double with realtype in the RAJA vector test functions.

In addition to the changes above, minor corrections were also made to the example programs, build system, and user documentation.

#### Changes in v3.1.0

Added NVECTOR print functions that write vector data to a specified file (e.g., N\_VPrintFile\_Serial).

Added make test and make test\_install options to the build system for testing SUNDIALS after building with make and installing with make install respectively.

#### Changes in v3.0.0

All interfaces to matrix structures and linear solvers have been reworked, and all example programs have been updated. The goal of the redesign of these interfaces was to provide more encapsulation and ease in interfacing custom linear solvers and interoperability with linear solver libraries. Specific changes include:

- Added generic SUNMATRIX module with three provided implementations: dense, banded and sparse. These replicate previous SUNDIALS Dls and Sls matrix structures in a single objectoriented API.
- Added example problems demonstrating use of generic SUNMATRIX modules.
- Added generic SUNLINEARSOLVER module with eleven provided implementations: dense, banded, LAPACK dense, LAPACK band, KLU, SuperLU\_MT, SPGMR, SPBCGS, SPTFQMR, SPFGMR, PCG. These replicate previous SUNDIALS generic linear solvers in a single objectoriented API.
- Added example problems demonstrating use of generic SUNLINEARSOLVER modules.
- Expanded package-provided direct linear solver (Dls) interfaces and scaled, preconditioned, iterative linear solver (Spils) interfaces to utilize generic SUNMATRIX and SUNLINEARSOLVER objects.
- Removed package-specific, linear solver-specific, solver modules (e.g. CVDENSE, KINBAND, IDAKLU, ARKSPGMR) since their functionality is entirely replicated by the generic Dls/Spils interfaces and SUNLINEARSOLVER/SUNMATRIX modules. The exception is CVDIAG, a diagonal approximate Jacobian solver available to CVODE and CVODES.
- Converted all SUNDIALS example problems to utilize new generic SUNMATRIX and SUNLIN-EARSOLVER objects, along with updated Dls and Spils linear solver interfaces.

• Added Spils interface routines to ARKode, CVODE, CVODES, IDA and IDAS to allow specification of a user-provided "JTSetup" routine. This change supports users who wish to set up data structures for the user-provided Jacobian-times-vector ("JTimes") routine, and where the cost of one JTSetup setup per Newton iteration can be amortized between multiple JTimes calls.

Two additional NVECTOR implementations were added – one for CUDA and one for RAJA vectors. These vectors are supplied to provide very basic support for running on GPU architectures. Users are advised that these vectors both move all data to the GPU device upon construction, and speedup will only be realized if the user also conducts the right-hand-side function evaluation on the device. In addition, these vectors assume the problem fits on one GPU. Further information about RAJA, users are referred to th web site, https://software.llnl.gov/RAJA/. These additions are accompanied by additions to various interface functions and to user documentation.

All indices for data structures were updated to a new sunindextype that can be configured to be a 32- or 64-bit integer data index type. sunindextype is defined to be int32\_t or int64\_t when portable types are supported, otherwise it is defined as int or long int. The Fortran interfaces continue to use long int for indices, except for their sparse matrix interface that now uses the new sunindextype. This new flexible capability for index types includes interfaces to PETSc, hypre, SuperLU\_MT, and KLU with either 32-bit or 64-bit capabilities depending how the user configures SUNDIALS.

To avoid potential namespace conflicts, the macros defining booleantype values TRUE and FALSE have been changed to SUNTRUE and SUNFALSE respectively.

Temporary vectors were removed from preconditioner setup and solve routines for all packages. It is assumed that all necessary data for user-provided preconditioner operations will be allocated and stored in user-provided data structures.

The file include/sundials\_fconfig.h was added. This file contains SUNDIALS type information for use in Fortran programs.

Added functions SUNDIALSGetVersion and SUNDIALSGetVersionNumber to get SUNDIALS release version information at runtime.

The build system was expanded to support many of the xSDK-compliant keys. The xSDK is a movement in scientific software to provide a foundation for the rapid and efficient production of high-quality, sustainable extreme-scale scientific applications. More information can be found at, https://xsdk.info.

In addition, numerous changes were made to the build system. These include the addition of separate BLAS\_ENABLE and BLAS\_LIBRARIES CMake variables, additional error checking during CMake configuration, minor bug fixes, and renaming CMake options to enable/disable examples for greater clarity and an added option to enable/disable Fortran 77 examples. These changes included changing EXAMPLES\_ENABLE to EXAMPLES\_ENABLE\_C, changing CXX\_ENABLE to EXAMPLES\_ENABLE\_CXX, changing F90\_ENABLE to EXAMPLES\_ENABLE\_F90, and adding an EXAMPLES\_ENABLE\_F77 option.

A bug fix was made in CVodeFree to call 1free unconditionally (if non-NULL).

Corrections and additions were made to the examples, to installation-related files, and to the user documentation.

#### Changes in v2.9.0

Two additional NVECTOR implementations were added – one for Hypre (parallel) ParVector vectors, and one for PETSc vectors. These additions are accompanied by additions to various interface functions and to user documentation.

Each NVECTOR module now includes a function,  $N\_VGetVectorID$ , that returns the NVECTOR module name.

A bug was fixed in the interpolation functions used in solving backward problems for adjoint sensitivity analysis.

For each linear solver, the various solver performance counters are now initialized to 0 in both the solver specification function and in solver limit function. This ensures that these solver counters are initialized upon linear solver instantiation as well as at the beginning of the problem solution.

6 Introduction

A memory leak was fixed in the banded preconditioner interface. In addition, updates were done to return integers from linear solver and preconditioner 'free' functions.

The Krylov linear solver Bi-CGstab was enhanced by removing a redundant dot product. Various additions and corrections were made to the interfaces to the sparse solvers KLU and SuperLU\_MT, including support for CSR format when using KLU.

In interpolation routines for backward problems, added logic to bypass sensitivity interpolation if input sensitivity argument is NULL.

New examples were added for use of sparse direct solvers within sensitivity integrations and for use of openMP.

Minor corrections and additions were made to the CVODES solver, to the examples, to installation-related files, and to the user documentation.

#### Changes in v2.8.0

Two major additions were made to the linear system solvers that are available for use with the CVODES solver. First, in the serial case, an interface to the sparse direct solver KLU was added. Second, an interface to SuperLU\_MT, the multi-threaded version of SuperLU, was added as a thread-parallel sparse direct solver option, to be used with the serial version of the NVECTOR module. As part of these additions, a sparse matrix (CSC format) structure was added to CVODES.

Otherwise, only relatively minor modifications were made to the CVODES solver:

In cvRootfind, a minor bug was corrected, where the input array rootdir was ignored, and a line was added to break out of root-search loop if the initial interval size is below the tolerance ttol.

In CVLapackBand, the line smu = MIN(N-1,mu+ml) was changed to smu = mu + ml to correct an illegal input error for DGBTRF/DGBTRS.

Some minor changes were made in order to minimize the differences between the sources for private functions in CVODES and CVODE.

An option was added in the case of Adjoint Sensitivity Analysis with dense or banded Jacobian: With a call to CVDlsSetDenseJacFnBS or CVDlsSetBandJacFnBS, the user can specify a user-supplied Jacobian function of type CVDls\*\*\*JacFnBS, for the case where the backward problem depends on the forward sensitivities.

In CVodeQuadSensInit, the line cv\_mem->cv\_fQS\_data = ... was corrected (missing Q).

In the User Guide, a paragraph was added in Section 6.2.1 on CVodeAdjReInit, and a paragraph was added in Section 6.2.9 on CVodeGetAdjY. In the example cvsRoberts\_ASAi\_dns, the output was revised to include the use of CVodeGetAdjY.

Two minor bugs were fixed regarding the testing of input on the first call to CVode – one involving tstop and one involving the initialization of \*tret.

For the Adjoint Sensitivity Analysis case in which the backward problem depends on the forward sensitivities, options have been added to allow for user-supplied pset, psolve, and jtimes functions.

In order to avoid possible name conflicts, the mathematical macro and function names MIN, MAX, SQR, RAbs, RSqrt, RExp, RPowerI, and RPowerR were changed to SUNMIN, SUNMAX, SUNSQR, SUNRabs, SUNRsqrt, SUNRexp, SRpowerI, and SUNRpowerR, respectively. These names occur in both the solver and example programs.

In the example cvsHessian\_ASA\_FSA, an error was corrected in the function fB2: y2 in place of y3 in the third term of Ith(yBdot,6).

Two new NVECTOR modules have been added for thread-parallel computing environments — one for openMP, denoted NVECTOR\_OPENMP, and one for Pthreads, denoted NVECTOR\_PTHREADS.

With this version of SUNDIALS, support and documentation of the Autotools mode of installation is being dropped, in favor of the CMake mode, which is considered more widely portable.

#### Changes in v2.7.0

One significant design change was made with this release: The problem size and its relatives, bandwidth parameters, related internal indices, pivot arrays, and the optional output lsflag have all been changed from type int to type long int, except for the problem size and bandwidths in user

calls to routines specifying BLAS/LAPACK routines for the dense/band linear solvers. The function NewIntArray is replaced by a pair NewIntArray/NewLintArray, for int and long int arrays, respectively. In a minor change to the user interface, the type of the index which in CVODES was changed from long int to int.

Errors in the logic for the integration of backward problems were identified and fixed.

A large number of minor errors have been fixed. Among these are the following: In CVSetTqBDF, the logic was changed to avoid a divide by zero. After the solver memory is created, it is set to zero before being filled. In each linear solver interface function, the linear solver memory is freed on an error return, and the \*\*Free function now includes a line setting to NULL the main memory pointer to the linear solver memory. In the rootfinding functions CVRcheck1/CVRcheck2, when an exact zero is found, the array glo of g values at the left endpoint is adjusted, instead of shifting the t location tlo slightly. In the installation files, we modified the treatment of the macro SUNDIALS\_USE\_GENERIC\_MATH, so that the parameter GENERIC\_MATH\_LIB is either defined (with no value) or not defined.

#### Changes in v2.6.0

Two new features related to the integration of ODE IVP problems were added in this release: (a) a new linear solver module, based on Blas and Lapack for both dense and banded matrices, and (b) an option to specify which direction of zero-crossing is to be monitored while performing rootfinding.

This version also includes several new features related to sensitivity analysis, among which are: (a) support for integration of quadrature equations depending on both the states and forward sensitivity (and thus support for forward sensitivity analysis of quadrature equations), (b) support for simultaneous integration of multiple backward problems based on the same underlying ODE (e.g., for use in an forward-over-adjoint method for computing second order derivative information), (c) support for backward integration of ODEs and quadratures depending on both forward states and sensitivities (e.g., for use in computing second-order derivative information), and (d) support for reinitialization of the adjoint module.

The user interface has been further refined. Some of the API changes involve: (a) a reorganization of all linear solver modules into two families (besides the existing family of scaled preconditioned iterative linear solvers, the direct solvers, including the new Lapack-based ones, were also organized into a direct family); (b) maintaining a single pointer to user data, optionally specified through a Set-type function; and (c) a general streamlining of the preconditioner modules distributed with the solver. Moreover, the prototypes of all functions related to integration of backward problems were modified to support the simultaneous integration of multiple problems. All backward problems defined by the user are internally managed through a linked list and identified in the user interface through a unique identifier.

#### Changes in v2.5.0

The main changes in this release involve a rearrangement of the entire SUNDIALS source tree (see §3.1). At the user interface level, the main impact is in the mechanism of including SUNDIALS header files which must now include the relative path (e.g. #include <cvode/cvode.h>). Additional changes were made to the build system: all exported header files are now installed in separate subdirectories of the instaltion *include* directory.

In the adjoint solver module, the following two bugs were fixed: in CVodeF the solver was sometimes incorrectly taking an additional step before returning control to the user (in CV\_NORMAL mode) thus leading to a failure in the interpolated output function; in CVodeB, while searching for the current check point, the solver was sometimes reaching outside the integration interval resulting in a segmentation fault.

The functions in the generic dense linear solver (sundials\_dense and sundials\_smalldense) were modified to work for rectangular  $m \times n$  matrices ( $m \le n$ ), while the factorization and solution functions were renamed to DenseGETRF/denGETRF and DenseGETRS/denGETRS, respectively. The factorization and solution functions in the generic band linear solver were renamed BandGBTRF and BandGBTRS, respectively.

8 Introduction

#### Changes in v2.4.0

CVSPBCG and CVSPTFQMR modules have been added to interface with the Scaled Preconditioned Bi-CGstab (SPBCGS) and Scaled Preconditioned Transpose-Free Quasi-Minimal Residual (SPTFQMR) linear solver modules, respectively (for details see Chapter 4). At the same time, function type names for Scaled Preconditioned Iterative Linear Solvers were added for the user-supplied Jacobian-times-vector and preconditioner setup and solve functions.

A new interpolation method was added to the CVODES adjoint module. The function CVadjMalloc has an additional argument which can be used to select the desired interpolation scheme.

The deallocation functions now take as arguments the address of the respective memory block pointer.

To reduce the possibility of conflicts, the names of all header files have been changed by adding unique prefixes (cvodes\_ and sundials\_). When using the default installation procedure, the header files are exported under various subdirectories of the target include directory. For more details see Appendix A.

#### Changes in v2.3.0

A minor bug was fixed in the interpolation functions of the adjoint CVODES module.

#### Changes in v2.2.0

The user interface has been further refined. Several functions used for setting optional inputs were combined into a single one. An optional user-supplied routine for setting the error weight vector was added. Additionally, to resolve potential variable scope issues, all SUNDIALS solvers release user data right after its use. The build systems has been further improved to make it more robust.

#### Changes in v2.1.2

A bug was fixed in the CVode function that was potentially leading to erroneous behaviour of the rootfinding procedure on the integration first step.

#### Changes in v2.1.1

This CVODES release includes bug fixes related to forward sensitivity computations (possible loss of accuray on a BDF order increase and incorrect logic in testing user-supplied absolute tolerances). In addition, we have added the option of activating and deactivating forward sensitivity calculations on successive CVODES runs without memory allocation/deallocation.

Other changes in this minor SUNDIALS release affect the build system.

#### Changes in v2.1.0

The major changes from the previous version involve a redesign of the user interface across the entire SUNDIALS suite. We have eliminated the mechanism of providing optional inputs and extracting optional statistics from the solver through the iopt and ropt arrays. Instead, CVODES now provides a set of routines (with prefix CVodeSet) to change the default values for various quantities controlling the solver and a set of extraction routines (with prefix CVodeGet) to extract statistics after return from the main solver routine. Similarly, each linear solver module provides its own set of Set- and Get-type routines. For more details see §4.5.6 and §4.5.8.

Additionally, the interfaces to several user-supplied routines (such as those providing Jacobians, preconditioner information, and sensitivity right hand sides) were simplified by reducing the number of arguments. The same information that was previously accessible through such arguments can now be obtained through Get-type functions.

The rootfinding feature was added, whereby the roots of a set of given functions may be computed during the integration of the ODE system.

Installation of CVODES (and all of SUNDIALS) has been completely redesigned and is now based on configure scripts.

#### 1.3 Reading this User Guide

This user guide is a combination of general usage instructions. Specific example programs are provided as a separate document. We expect that some readers will want to concentrate on the general instructions, while others will refer mostly to the examples, and the organization is intended to accommodate both styles.

There are different possible levels of usage of CVODES. The most casual user, with a small IVP problem only, can get by with reading §2.1, then Chapter 4 through §4.5.5 only, and looking at examples in [35]. In addition, to solve a forward sensitivity problem the user should read §2.6, followed by Chapter 5 through §5.2.4 only, and look at examples in [35].

In a different direction, a more expert user with an IVP problem may want to (a) use a package preconditioner ( $\S4.8$ ), (b) supply his/her own Jacobian or preconditioner routines ( $\S4.6$ ), (c) do multiple runs of problems of the same size ( $\S4.5.9$ ), (d) supply a new NVECTOR module (Chapter 7), or even (e) supply new SUNLINSOL and/or SUNMATRIX modules (Chapters 8 and 9). An advanced user with a forward sensitivity problem may also want to (a) provide his/her own sensitivity equations right-hand side routine ( $\S5.3$ ), (b) perform multiple runs with the same number of sensitivity parameters ( $\S5.2.1$ ), or (c) extract additional diagnostic information ( $\S5.2.4$ ). A user with an adjoint sensitivity problem needs to understand the IVP solution approach at the desired level and also go through  $\S2.7$  for a short mathematical description of the adjoint approach, Chapter 6 for the usage of the adjoint module in CVODES, and the examples in [35].

The structure of this document is as follows:

- In Chapter 2, we give short descriptions of the numerical methods implemented by CVODES for the solution of initial value problems for systems of ODEs, continue with short descriptions of preconditioning (§2.2), stability limit detection (§2.3), and rootfinding (§2.4), and conclude with an overview of the mathematical aspects of sensitivity analysis, both forward (§2.6) and adjoint (§2.7).
- The following chapter describes the structure of the SUNDIALS suite of solvers (§3.1) and the software organization of the CVODES solver (§3.2).
- Chapter 4 is the main usage document for CVODES for simulation applications. It includes a complete description of the user interface for the integration of ODE initial value problems. Readers that are not interested in using CVODES for sensitivity analysis can then skip the next two chapters.
- Chapter 5 describes the usage of CVODES for forward sensitivity analysis as an extension of its IVP integration capabilities. We begin with a skeleton of the user main program, with emphasis on the steps that are required in addition to those already described in Chapter 4. Following that we provide detailed descriptions of the user-callable interface routines specific to forward sensitivity analysis and of the additional optional user-defined routines.
- Chapter 6 describes the usage of CVODES for adjoint sensitivity analysis. We begin by describing the CVODES checkpointing implementation for interpolation of the original IVP solution during integration of the adjoint system backward in time, and with an overview of a user's main program. Following that we provide complete descriptions of the user-callable interface routines for adjoint sensitivity analysis as well as descriptions of the required additional user-defined routines.
- Chapter 7 gives a brief overview of the generic NVECTOR module shared among the various components of SUNDIALS, and details on the NVECTOR implementations provided with SUNDIALS.

10 Introduction

• Chapter 8 gives a brief overview of the generic SUNMATRIX module shared among the various components of SUNDIALS, and details on the SUNMATRIX implementations provided with SUNDIALS: a dense implementation (§8.1), a banded implementation (§8.2) and a sparse implementation (§8.3).

- Chapter 9 gives a brief overview of the generic Sunlinsol module shared among the various components of Sundials. This chapter contains details on the Sunlinsol implementations provided with Sundials. The chapter also contains details on the Sunlinsol implementations provided with Sundials that interface with external linear solver libraries.
- Finally, in the appendices, we provide detailed instructions for the installation of CVODES, within the structure of SUNDIALS (Appendix A), as well as a list of all the constants used for input to and output from CVODES functions (Appendix B).

Finally, the reader should be aware of the following notational conventions in this user guide: program listings and identifiers (such as CVodeInit) within textual explanations appear in typewriter type style; fields in C structures (such as content) appear in italics; and packages or modules, such as CVDLS, are written in all capitals. Usage and installation instructions that constitute important warnings are marked with a triangular symbol in the margin.

#### 1.4 SUNDIALS Release License

The SUNDIALS packages are released open source, under a BSD license. The only requirements of the BSD license are preservation of copyright and a standard disclaimer of liability. Our Copyright notice is below along with the license.

\*\*PLEASE NOTE\*\* If you are using SUNDIALS with any third party libraries linked in (e.g., LaPACK, KLU, SuperLU\_MT, PETSc, or hypre), be sure to review the respective license of the package as that license may have more restrictive terms than the SUNDIALS license. For example, if someone builds SUNDIALS with a statically linked KLU, the build is subject to terms of the LGPL license (which is what KLU is released with) and \*not\* the SUNDIALS BSD license anymore.

#### 1.4.1 Copyright Notices

All SUNDIALS packages except ARKode are subject to the following Copyright notice.

#### 1.4.1.1 SUNDIALS Copyright

# Chapter 2

# Mathematical Considerations

CVODES solves ODE initial value problems (IVPs) in real N-space, which we write in the abstract form

$$\dot{y} = f(t, y), \quad y(t_0) = y_0,$$
 (2.1)

where  $y \in \mathbf{R}^N$ . Here we use  $\dot{y}$  to denote dy/dt. While we use t to denote the independent variable, and usually this is time, it certainly need not be. CVODES solves both stiff and non-stiff systems. Roughly speaking, stiffness is characterized by the presence of at least one rapidly damped mode, whose time constant is small compared to the time scale of the solution itself.

Additionally, if (2.1) depends on some parameters  $p \in \mathbf{R}^{N_p}$ , i.e.

$$\dot{y} = f(t, y, p)$$
  
 $y(t_0) = y_0(p)$ , (2.2)

CVODES can also compute first order derivative information, performing either forward sensitivity analysis or adjoint sensitivity analysis. In the first case, CVODES computes the sensitivities of the solution with respect to the parameters p, while in the second case, CVODES computes the gradient of a derived function with respect to the parameters p.

### 2.1 IVP solution

The methods used in CVODES are variable-order, variable-step multistep methods, based on formulas of the form

$$\sum_{i=0}^{K_1} \alpha_{n,i} y^{n-i} + h_n \sum_{i=0}^{K_2} \beta_{n,i} \dot{y}^{n-i} = 0.$$
 (2.3)

Here the  $y^n$  are computed approximations to  $y(t_n)$ , and  $h_n = t_n - t_{n-1}$  is the step size. The user of CVODE must choose appropriately one of two multistep methods. For nonstiff problems, CVODE includes the Adams-Moulton formulas, characterized by  $K_1 = 1$  and  $K_2 = q$  above, where the order q varies between 1 and 12. For stiff problems, CVODEs includes the Backward Differentiation Formulas (BDF) in so-called fixed-leading coefficient (FLC) form, given by  $K_1 = q$  and  $K_2 = 0$ , with order q varying between 1 and 5. The coefficients are uniquely determined by the method type, its order, the recent history of the step sizes, and the normalization  $\alpha_{n,0} = -1$ . See [6] and [25].

For either choice of formula, the nonlinear system

$$G(y^n) \equiv y^n - h_n \beta_{n,0} f(t_n, y^n) - a_n = 0, \qquad (2.4)$$

where  $a_n \equiv \sum_{i>0} (\alpha_{n,i} y^{n-i} + h_n \beta_{n,i} \dot{y}^{n-i})$ , must be solved (approximately) at each integration step. For this, CVODES offers the choice of either functional iteration, suitable only for nonstiff systems, and various versions of Newton iteration. Functional iteration, given by

$$y^{n(m+1)} = h_n \beta_{n,0} f(t_n, y^{n(m)}) + a_n,$$

involves evaluations of f only. In contrast, Newton iteration requires the solution of linear systems

$$M[y^{n(m+1)} - y^{n(m)}] = -G(y^{n(m)}), (2.5)$$

in which

$$M \approx I - \gamma J$$
,  $J = \partial f / \partial y$ , and  $\gamma = h_n \beta_{n,0}$ . (2.6)

The initial guess for the iteration is a predicted value  $y^{n(0)}$  computed explicitly from the available history data.

For the solution of the linear systems within the Newton corrections, CVODES provides several choices, including the option of an user-supplied linear solver module. The linear solver modules distributed with SUNDIALS are organized in two families, a *direct* family comprising direct linear solvers for dense, banded or sparse matrices, and a *spils* family comprising scaled preconditioned iterative (Krylov) linear solvers. The methods offered through these modules are as follows:

- dense direct solvers, using either an internal implementation or a Blas/Lapack implementation (serial or threaded vector modules only),
- band direct solvers, using either an internal implementation or a Blas/Lapack implementation (serial or threaded vector modules only),
- sparse direct solver interfaces, using either the KLU sparse solver library [11, 1], or the threadenabled SuperLU\_MT sparse solver library [27, 12, 2] (serial or threaded vector modules only) [Note that users will need to download and install the KLU or SUPERLUMT packages independent of CVODES],
- SPGMR, a scaled preconditioned GMRES (Generalized Minimal Residual method) solver,
- SPFGMR, a scaled preconditioned FGMRES (Flexible Generalized Minimal Residual method) solver.
- SPBCGS, a scaled preconditioned Bi-CGStab (Bi-Conjugate Gradient Stable method) solver,
- SPTFQMR, a scaled preconditioned TFQMR (Transpose-Free Quasi-Minimal Residual method) solver, or
- PCG, a scaled preconditioned CG (Conjugate Gradient method) solver.

For large stiff systems, where direct methods are not feasible, the combination of a BDF integrator and a preconditioned Krylov method yields a powerful tool because it combines established methods for stiff integration, nonlinear iteration, and Krylov (linear) iteration with a problem-specific treatment of the dominant source of stiffness, in the form of the user-supplied preconditioner matrix [4].

In addition, CVODE also provides a linear solver module which only uses a diagonal approximation of the Jacobian matrix.

Note that the dense, band and sparse direct linear solvers can only be used with the serial and threaded vector representations. The diagonal solver can be used with any vector representation.

In the process of controlling errors at various levels, CVODES uses a weighted root-mean-square norm, denoted  $\|\cdot\|_{WRMS}$ , for all error-like quantities. The multiplicative weights used are based on the current solution and on the relative and absolute tolerances input by the user, namely

$$W_i = 1/[\text{RTOL} \cdot |y_i| + \text{ATOL}_i]. \tag{2.7}$$

Because  $1/W_i$  represents a tolerance in the component  $y_i$ , a vector whose norm is 1 is regarded as "small." For brevity, we will usually drop the subscript WRMS on norms in what follows.

In the cases of a direct solver (dense, band, sparse, or diagonal), the iteration is a Modified Newton iteration, in that the iteration matrix M is fixed throughout the nonlinear iterations. However, for any of the Krylov methods, it is an Inexact Newton iteration, in which M is applied in a matrix-free manner, with matrix-vector products Jv obtained by either difference quotients or a user-supplied routine. The matrix M (direct cases) or preconditioner matrix P (Krylov cases) is updated as infrequently as possible to balance the high costs of matrix operations against other costs. Specifically, this matrix update occurs when:

2.1 IVP solution 15

- starting the problem,
- more than 20 steps have been taken since the last update,
- the value  $\bar{\gamma}$  of  $\gamma$  at the last update satisfies  $|\gamma/\bar{\gamma}-1|>0.3$ ,
- a non-fatal convergence failure just occurred, or
- an error test failure just occurred.

When forced by a convergence failure, an update of M or P may or may not involve a reevaluation of J (in M) or of Jacobian data (in P), depending on whether Jacobian error was the likely cause of the failure. More generally, the decision is made to reevaluate J (or instruct the user to reevaluate Jacobian data in P) when:

- starting the problem,
- more than 50 steps have been taken since the last evaluation,
- a convergence failure occurred with an outdated matrix, and the value  $\bar{\gamma}$  of  $\gamma$  at the last update satisfies  $|\gamma/\bar{\gamma}-1| < 0.2$ , or
- a convergence failure occurred that forced a step size reduction.

The stopping test for the Newton iteration is related to the subsequent local error test, with the goal of keeping the nonlinear iteration errors from interfering with local error control. As described below, the final computed value  $y^{n(m)}$  will have to satisfy a local error test  $||y^{n(m)}-y^{n(0)}|| \leq \epsilon$ . Letting  $y^n$  denote the exact solution of (2.4), we want to ensure that the iteration error  $y^n - y^{n(m)}$  is small relative to  $\epsilon$ , specifically that it is less than  $0.1\epsilon$ . (The safety factor 0.1 can be changed by the user.) For this, we also estimate the linear convergence rate constant R as follows. We initialize R to 1, and reset R = 1 when M or P is updated. After computing a correction  $\delta_m = y^{n(m)} - y^{n(m-1)}$ , we update R if m > 1 as

$$R \leftarrow \max\{0.3R, \|\delta_m\|/\|\delta_{m-1}\|\}$$
.

Now we use the estimate

$$||y^n - y^{n(m)}|| \approx ||y^{n(m+1)} - y^{n(m)}|| \approx R||y^{n(m)} - y^{n(m-1)}|| = R||\delta_m||.$$

Therefore the convergence (stopping) test is

$$R\|\delta_m\| < 0.1\epsilon$$
.

We allow at most 3 iterations (but this limit can be changed by the user). We also declare the iteration diverged if any  $\|\delta_m\|/\|\delta_{m-1}\| > 2$  with m > 1. If convergence fails with J or P current, we are forced to reduce the step size, and we replace  $h_n$  by  $h_n/4$ . The integration is halted after a preset number of convergence failures; the default value of this limit is 10, but this can be changed by the user.

When a Krylov method is used to solve the linear system, its errors must also be controlled, and this also involves the local error test constant. The linear iteration error in the solution vector  $\delta_m$  is approximated by the preconditioned residual vector. Thus to ensure (or attempt to ensure) that the linear iteration errors do not interfere with the nonlinear error and local integration error controls, we require that the norm of the preconditioned residual be less than  $0.05 \cdot (0.1\epsilon)$ .

With the direct dense and band methods, the Jacobian may be supplied by a user routine, or approximated by difference quotients, at the user's option. In the latter case, we use the usual approximation

$$J_{ij} = [f_i(t, y + \sigma_j e_j) - f_i(t, y)]/\sigma_j.$$

The increments  $\sigma_i$  are given by

$$\sigma_j = \max \left\{ \sqrt{U} |y_j|, \sigma_0/W_j \right\},$$

where U is the unit roundoff,  $\sigma_0$  is a dimensionless value, and  $W_j$  is the error weight defined in (2.7). In the dense case, this scheme requires N evaluations of f, one for each column of J. In the band case, the columns of J are computed in groups, by the Curtis-Powell-Reid algorithm, with the number of f evaluations equal to the bandwidth.

We note that with the sparse direct solvers, the Jacobian must be supplied by a user routine.

In the case of a Krylov method, preconditioning may be used on the left, on the right, or both, with user-supplied routines for the preconditioning setup and solve operations, and optionally also for the required matrix-vector products Jv. If a routine for Jv is not supplied, these products are computed as

$$Jv = [f(t, y + \sigma v) - f(t, y)]/\sigma.$$
(2.8)

The increment  $\sigma$  is 1/||v||, so that  $\sigma v$  has norm 1.

A critical part of CVODES — making it an ODE "solver" rather than just an ODE method, is its control of local error. At every step, the local error is estimated and required to satisfy tolerance conditions, and the step is redone with reduced step size whenever that error test fails. As with any linear multistep method, the local truncation error LTE, at order q and step size h, satisfies an asymptotic relation

$$LTE = Ch^{q+1}y^{(q+1)} + O(h^{q+2})$$

for some constant C, under mild assumptions on the step sizes. A similar relation holds for the error in the predictor  $y^{n(0)}$ . These are combined to get a relation

LTE = 
$$C'[y^n - y^{n(0)}] + O(h^{q+2})$$
.

The local error test is simply  $\|\text{LTE}\| \le 1$ . Using the above, it is performed on the predictor-corrector difference  $\Delta_n \equiv y^{n(m)} - y^{n(0)}$  (with  $y^{n(m)}$  the final iterate computed), and takes the form

$$\|\Delta_n\| \le \epsilon \equiv 1/|C'|$$
.

If this test passes, the step is considered successful. If it fails, the step is rejected and a new step size h' is computed based on the asymptotic behavior of the local error, namely by the equation

$$(h'/h)^{q+1} \|\Delta_n\| = \epsilon/6.$$

Here 1/6 is a safety factor. A new attempt at the step is made, and the error test repeated. If it fails three times, the order q is reset to 1 (if q > 1), or the step is restarted from scratch (if q = 1). The ratio h'/h is limited above to 0.2 after two error test failures, and limited below to 0.1 after three. After seven failures, CVODES returns to the user with a give-up message.

In addition to adjusting the step size to meet the local error test, CVODE periodically adjusts the order, with the goal of maximizing the step size. The integration starts out at order 1 and varies the order dynamically after that. The basic idea is to pick the order q for which a polynomial of order q best fits the discrete data involved in the multistep method. However, if either a convergence failure or an error test failure occurred on the step just completed, no change in step size or order is done. At the current order q, selecting a new step size is done exactly as when the error test fails, giving a tentative step size ratio

$$h'/h = (\epsilon/6||\Delta_n||)^{1/(q+1)} \equiv \eta_q.$$

We consider changing order only after taking q + 1 steps at order q, and then we consider only orders q' = q - 1 (if q > 1) or q' = q + 1 (if q < 5). The local truncation error at order q' is estimated using the history data. Then a tentative step size ratio is computed on the basis that this error, LTE(q'), behaves asymptotically as  $h^{q'+1}$ . With safety factors of 1/6 and 1/10 respectively, these ratios are:

$$h'/h = [1/6||\text{LTE}(q-1)||]^{1/q} \equiv \eta_{q-1}$$

and

$$h'/h = [1/10 \| \text{LTE}(q+1) \|]^{1/(q+2)} \equiv \eta_{q+1}$$
.

The new order and step size are then set according to

$$\eta = \max\{\eta_{q-1}, \eta_q, \eta_{q+1}\}, \quad h' = \eta h,$$

with q' set to the index achieving the above maximum. However, if we find that  $\eta < 1.5$ , we do not bother with the change. Also, h'/h is always limited to 10, except on the first step, when it is limited to  $10^4$ .

The various algorithmic features of CVODES described above, as inherited from VODE and VODPK, are documented in [3, 5, 19]. They are also summarized in [20].

CVODES permits the user to impose optional inequality constraints on individual components of the solution vector y. Any of the following four constraints can be imposed:  $y_i > 0$ ,  $y_i < 0$ ,  $y_i \geq 0$ , or  $y_i \leq 0$ . The constraint satisfaction is tested after a successful nonlinear system solution. If any constraint fails, we declare a convergence failure of the Newton iteration and reduce the step size. Rather than cutting the step size by some arbitrary factor, CVODES estimates a new step size h' using a linear approximation of the components in y that failed the constraint test (including a afety factor of 0.9 to cover the strict inequality case).

Normally, CVODES takes steps until a user-defined output value  $t = t_{\text{out}}$  is overtaken, and then it computes  $y(t_{\text{out}})$  by interpolation. However, a "one step" mode option is available, where control returns to the calling program after each step. There are also options to force CVODES not to integrate past a given stopping point  $t = t_{\text{stop}}$ .

#### 2.2 Preconditioning

When using a Newton method to solve the nonlinear system (2.4), CVODES makes repeated use of a linear solver to solve linear systems of the form Mx = -r, where x is a correction vector and r is a residual vector. If this linear system solve is done with one of the scaled preconditioned iterative linear solvers, these solvers are rarely successful if used without preconditioning; it is generally necessary to precondition the system in order to obtain acceptable efficiency. A system Ax = b can be preconditioned on the left, as  $(P^{-1}A)x = P^{-1}b$ ; on the right, as  $(AP^{-1})Px = b$ ; or on both sides, as  $(P_L^{-1}AP_R^{-1})P_Rx = P_L^{-1}b$ . The Krylov method is then applied to a system with the matrix  $P^{-1}A$ , or  $AP^{-1}$ , or  $P_L^{-1}AP_R^{-1}$ , instead of A. In order to improve the convergence of the Krylov iteration, the preconditioner matrix P, or the product  $P_LP_R$  in the last case, should in some sense approximate the system matrix P. Yet at the same time, in order to be cost-effective, the matrix P, or matrices  $P_L$  and  $P_R$ , should be reasonably efficient to evaluate and solve. Finding a good point in this tradeoff between rapid convergence and low cost can be very difficult. Good choices are often problem-dependent (for example, see [4] for an extensive study of preconditioners for reaction-transport systems).

Most of the iterative linear solvers supplied with SUNDIALS allow for preconditioning either side, or on both sides, although we know of no situation where preconditioning on both sides is clearly superior to preconditioning on one side only (with the product  $P_L P_R$ ). Moreover, for a given preconditioner matrix, the merits of left vs. right preconditioning are unclear in general, and the user should experiment with both choices. Performance will differ because the inverse of the left preconditioner is included in the linear system residual whose norm is being tested in the Krylov algorithm. As a rule, however, if the preconditioner is the product of two matrices, we recommend that preconditioning be done either on the left only or the right only, rather than using one factor on each side.

Typical preconditioners used with CVODES are based on approximations to the system Jacobian,  $J = \partial f/\partial y$ . Since the Newton iteration matrix involved is  $M = I - \gamma J$ , any approximation  $\bar{J}$  to J yields a matrix that is of potential use as a preconditioner, namely  $P = I - \gamma \bar{J}$ . Because the Krylov iteration occurs within a Newton iteration and further also within a time integration, and since each of these iterations has its own test for convergence, the preconditioner may use a very crude approximation, as long as it captures the dominant numerical feature(s) of the system. We have found that the combination of a preconditioner with the Newton-Krylov iteration, using even a fairly poor approximation to the Jacobian, can be surprisingly superior to using the same matrix without Krylov acceleration (i.e., a modified Newton iteration), as well as to using the Newton-Krylov method with no preconditioning.

#### 2.3 BDF stability limit detection

CVODES includes an algorithm, STALD (STAbility Limit Detection), which provides protection against potentially unstable behavior of the BDF multistep integration methods in certain situations, as described below.

When the BDF option is selected, CVODES uses Backward Differentiation Formula methods of orders 1 to 5. At order 1 or 2, the BDF method is A-stable, meaning that for any complex constant  $\lambda$  in the open left half-plane, the method is unconditionally stable (for any step size) for the standard scalar model problem  $\dot{y} = \lambda y$ . For an ODE system, this means that, roughly speaking, as long as all modes in the system are stable, the method is also stable for any choice of step size, at least in the sense of a local linear stability analysis.

At orders 3 to 5, the BDF methods are not A-stable, although they are stiffly stable. In each case, in order for the method to be stable at step size h on the scalar model problem, the product  $h\lambda$  must lie within a region of absolute stability. That region excludes a portion of the left half-plane that is concentrated near the imaginary axis. The size of that region of instability grows as the order increases from 3 to 5. What this means is that, when running BDF at any of these orders, if an eigenvalue  $\lambda$  of the system lies close enough to the imaginary axis, the step sizes h for which the method is stable are limited (at least according to the linear stability theory) to a set that prevents  $h\lambda$  from leaving the stability region. The meaning of close enough depends on the order. At order 3, the unstable region is much narrower than at order 5, so the potential for unstable behavior grows with order.

System eigenvalues that are likely to run into this instability are ones that correspond to weakly damped oscillations. A pure undamped oscillation corresponds to an eigenvalue on the imaginary axis. Problems with modes of that kind call for different considerations, since the oscillation generally must be followed by the solver, and this requires step sizes ( $h \sim 1/\nu$ , where  $\nu$  is the frequency) that are stable for BDF anyway. But for a weakly damped oscillatory mode, the oscillation in the solution is eventually damped to the noise level, and at that time it is important that the solver not be restricted to step sizes on the order of  $1/\nu$ . It is in this situation that the new option may be of great value.

In terms of partial differential equations, the typical problems for which the stability limit detection option is appropriate are ODE systems resulting from semi-discretized PDEs (i.e., PDEs discretized in space) with advection and diffusion, but with advection dominating over diffusion. Diffusion alone produces pure decay modes, while advection tends to produce undamped oscillatory modes. A mix of the two with advection dominant will have weakly damped oscillatory modes.

The STALD algorithm attempts to detect, in a direct manner, the presence of a stability region boundary that is limiting the step sizes in the presence of a weakly damped oscillation [17]. The algorithm supplements (but differs greatly from) the existing algorithms in CVODES for choosing step size and order based on estimated local truncation errors. The STALD algorithm works directly with history data that is readily available in CVODES. If it concludes that the step size is in fact stability-limited, it dictates a reduction in the method order, regardless of the outcome of the error-based algorithm. The STALD algorithm has been tested in combination with the VODE solver on linear advection-dominated advection-diffusion problems [18], where it works well. The implementation in CVODES has been successfully tested on linear and nonlinear advection-diffusion problems, among others.

This stability limit detection option adds some computational overhead to the CVODES solution. (In timing tests, these overhead costs have ranged from 2% to 7% of the total, depending on the size and complexity of the problem, with lower relative costs for larger problems.) Therefore, it should be activated only when there is reasonable expectation of modes in the user's system for which it is appropriate. In particular, if a CVODE solution with this option turned off appears to take an inordinately large number of steps at orders 3-5 for no apparent reason in terms of the solution time scale, then there is a good chance that step sizes are being limited by stability, and that turning on the option will improve the efficiency of the solution.

2.4 Rootfinding

#### 2.4 Rootfinding

The CVODES solver has been augmented to include a rootfinding feature. This means that, while integrating the Initial Value Problem (2.1), CVODES can also find the roots of a set of user-defined functions  $g_i(t, y)$  that depend both on t and on the solution vector y = y(t). The number of these root functions is arbitrary, and if more than one  $g_i$  is found to have a root in any given interval, the various root locations are found and reported in the order that they occur on the t axis, in the direction of integration.

Generally, this rootfinding feature finds only roots of odd multiplicity, corresponding to changes in sign of  $g_i(t, y(t))$ , denoted  $g_i(t)$  for short. If a user root function has a root of even multiplicity (no sign change), it will probably be missed by CVODES. If such a root is desired, the user should reformulate the root function so that it changes sign at the desired root.

The basic scheme used is to check for sign changes of any  $g_i(t)$  over each time step taken, and then (when a sign change is found) to hone in on the root(s) with a modified secant method [16]. In addition, each time g is computed, CVODES checks to see if  $g_i(t) = 0$  exactly, and if so it reports this as a root. However, if an exact zero of any  $g_i$  is found at a point t, CVODES computes g at  $t + \delta$  for a small increment  $\delta$ , slightly further in the direction of integration, and if any  $g_i(t+\delta) = 0$  also, CVODES stops and reports an error. This way, each time CVODES takes a time step, it is guaranteed that the values of all  $g_i$  are nonzero at some past value of t, beyond which a search for roots is to be done.

At any given time in the course of the time-stepping, after suitable checking and adjusting has been done, CVODES has an interval  $(t_{lo}, t_{hi}]$  in which roots of the  $g_i(t)$  are to be sought, such that  $t_{hi}$  is further ahead in the direction of integration, and all  $g_i(t_{lo}) \neq 0$ . The endpoint  $t_{hi}$  is either  $t_n$ , the end of the time step last taken, or the next requested output time  $t_{out}$  if this comes sooner. The endpoint  $t_{lo}$  is either  $t_{n-1}$ , the last output time  $t_{out}$  (if this occurred within the last step), or the last root location (if a root was just located within this step), possibly adjusted slightly toward  $t_n$  if an exact zero was found. The algorithm checks  $g_i$  at  $t_{hi}$  for zeros and for sign changes in  $(t_{lo}, t_{hi})$ . If no sign changes were found, then either a root is reported (if some  $g_i(t_{hi}) = 0$ ) or we proceed to the next time interval (starting at  $t_{hi}$ ). If one or more sign changes were found, then a loop is entered to locate the root to within a rather tight tolerance, given by

$$\tau = 100 * U * (|t_n| + |h|)$$
 (U = unit roundoff).

Whenever sign changes are seen in two or more root functions, the one deemed most likely to have its root occur first is the one with the largest value of  $|g_i(t_{hi})|/|g_i(t_{hi})-g_i(t_{lo})|$ , corresponding to the closest to  $t_{lo}$  of the secant method values. At each pass through the loop, a new value  $t_{mid}$  is set, strictly within the search interval, and the values of  $g_i(t_{mid})$  are checked. Then either  $t_{lo}$  or  $t_{hi}$  is reset to  $t_{mid}$  according to which subinterval is found to include the sign change. If there is none in  $(t_{lo}, t_{mid})$  but some  $g_i(t_{mid}) = 0$ , then that root is reported. The loop continues until  $|t_{hi} - t_{lo}| < \tau$ , and then the reported root location is  $t_{hi}$ .

In the loop to locate the root of  $g_i(t)$ , the formula for  $t_{mid}$  is

$$t_{mid} = t_{hi} - (t_{hi} - t_{lo})g_i(t_{hi})/[g_i(t_{hi}) - \alpha g_i(t_{lo})]$$

where  $\alpha$  is a weight parameter. On the first two passes through the loop,  $\alpha$  is set to 1, making  $t_{mid}$  the secant method value. Thereafter,  $\alpha$  is reset according to the side of the subinterval (low vs. high, i.e., toward  $t_{lo}$  vs. toward  $t_{hi}$ ) in which the sign change was found in the previous two passes. If the two sides were opposite,  $\alpha$  is set to 1. If the two sides were the same,  $\alpha$  is halved (if on the low side) or doubled (if on the high side). The value of  $t_{mid}$  is closer to  $t_{lo}$  when  $\alpha < 1$  and closer to  $t_{hi}$  when  $\alpha > 1$ . If the above value of  $t_{mid}$  is within  $\tau/2$  of  $t_{lo}$  or  $t_{hi}$ , it is adjusted inward, such that its fractional distance from the endpoint (relative to the interval size) is between .1 and .5 (.5 being the midpoint), and the actual distance from the endpoint is at least  $\tau/2$ .

#### 2.5 Pure quadrature integration

In many applications, and most notably during the backward integration phase of an adjoint sensitivity analysis run (see §2.7) it is of interest to compute integral quantities of the form

$$z(t) = \int_{t_0}^{t} q(\tau, y(\tau), p) d\tau.$$
 (2.9)

The most effective approach to compute z(t) is to extend the original problem with the additional ODEs (obtained by applying Leibnitz's differentiation rule):

$$\dot{z} = q(t, y, p), \quad z(t_0) = 0.$$
 (2.10)

Note that this is equivalent to using a quadrature method based on the underlying linear multistep polynomial representation for y(t).

This can be done at the "user level" by simply exposing to CVODES the extended ODE system (2.2)+(2.9). However, in the context of an implicit integration solver, this approach is not desirable since the nonlinear solver module will require the Jacobian (or Jacobian-vector product) of this extended ODE. Moreover, since the additional states z do not enter the right-hand side of the ODE (2.9) and therefore the right-hand side of the extended ODE system, it is much more efficient to treat the ODE system (2.9) separately from the original system (2.2) by "taking out" the additional states z from the nonlinear system (2.4) that must be solved in the correction step of the LMM. Instead, "corrected" values  $z^n$  are computed explicitly as

$$z^{n} = -\frac{1}{\alpha_{n,0}} \left( h_{n} \beta_{n,0} q(t_{n}, y_{n}, p) + h_{n} \sum_{i=1}^{K_{2}} \beta_{n,i} \dot{z}^{n-i} + \sum_{i=1}^{K_{1}} \alpha_{n,i} z^{n-i} \right),$$

once the new approximation  $y^n$  is available.

The quadrature variables z can be optionally included in the error test, in which case corresponding relative and absolute tolerances must be provided.

# 2.6 Forward sensitivity analysis

Typically, the governing equations of complex, large-scale models depend on various parameters, through the right-hand side vector and/or through the vector of initial conditions, as in (2.2). In addition to numerically solving the ODEs, it may be desirable to determine the sensitivity of the results with respect to the model parameters. Such sensitivity information can be used to estimate which parameters are most influential in affecting the behavior of the simulation or to evaluate optimization gradients (in the setting of dynamic optimization, parameter estimation, optimal control, etc.).

The solution sensitivity with respect to the model parameter  $p_i$  is defined as the vector  $s_i(t) = \partial y(t)/\partial p_i$  and satisfies the following forward sensitivity equations (or sensitivity equations for short):

$$\dot{s}_i = \frac{\partial f}{\partial y} s_i + \frac{\partial f}{\partial p_i}, \quad s_i(t_0) = \frac{\partial y_0(p)}{\partial p_i}, \qquad (2.11)$$

obtained by applying the chain rule of differentiation to the original ODEs (2.2).

When performing forward sensitivity analysis, CVODES carries out the time integration of the combined system, (2.2) and (2.11), by viewing it as an ODE system of size  $N(N_s+1)$ , where  $N_s$  is the number of model parameters  $p_i$ , with respect to which sensitivities are desired  $(N_s \leq N_p)$ . However, major improvements in efficiency can be made by taking advantage of the special form of the sensitivity equations as linearizations of the original ODEs. In particular, for stiff systems, for which CVODES employs a Newton iteration, the original ODE system and all sensitivity systems share the same Jacobian matrix, and therefore the same iteration matrix M in (2.6).

The sensitivity equations are solved with the same linear multistep formula that was selected for the original ODEs and, if Newton iteration was selected, the same linear solver is used in the correction phase for both state and sensitivity variables. In addition, CVODEs offers the option of including (full error control) or excluding (partial error control) the sensitivity variables from the local error test.

#### 2.6.1 Forward sensitivity methods

In what follows we briefly describe three methods that have been proposed for the solution of the combined ODE and sensitivity system for the vector  $\hat{y} = [y, s_1, \dots, s_{N_s}]$ .

#### • Staggered Direct

In this approach [9], the nonlinear system (2.4) is first solved and, once an acceptable numerical solution is obtained, the sensitivity variables at the new step are found by directly solving (2.11) after the (BDF or Adams) discretization is used to eliminate  $\dot{s}_i$ . Although the system matrix of the above linear system is based on exactly the same information as the matrix M in (2.6), it must be updated and factored at every step of the integration, in contrast to an evalutaion of M which is updated only occasionally. For problems with many parameters (relative to the problem size), the staggered direct method can outperform the methods described below [26]. However, the computational cost associated with matrix updates and factorizations makes this method unattractive for problems with many more states than parameters (such as those arising from semidiscretization of PDEs) and is therefore not implemented in CVODES.

#### • Simultaneous Corrector

In this method [28], the discretization is applied simultaneously to both the original equations (2.2) and the sensitivity systems (2.11) resulting in the following nonlinear system

$$\hat{G}(\hat{y}_n) \equiv \hat{y}_n - h_n \beta_{n,0} \hat{f}(t_n, \hat{y}_n) - \hat{a}_n = 0$$

where  $\hat{f} = [f(t, y, p), \dots, (\partial f/\partial y)(t, y, p)s_i + (\partial f/\partial p_i)(t, y, p), \dots]$ , and  $\hat{a}_n$  is comprised of the terms in the discretization that depend on the solution at previous integration steps. This combined nonlinear system can be solved using a modified Newton method as in (2.5) by solving the corrector equation

$$\hat{M}[\hat{y}_{n(m+1)} - \hat{y}_{n(m)}] = -\hat{G}(\hat{y}_{n(m)})$$
(2.12)

at each iteration, where

$$\hat{M} = \begin{bmatrix} M & & & & \\ -\gamma J_1 & M & & & \\ -\gamma J_2 & 0 & M & & \\ \vdots & \vdots & \ddots & \ddots & \\ -\gamma J_{N_s} & 0 & \dots & 0 & M \end{bmatrix},$$

M is defined as in (2.6), and  $J_i = (\partial/\partial y) \left[ (\partial f/\partial y) s_i + (\partial f/\partial p_i) \right]$ . It can be shown that 2-step quadratic convergence can be retained by using only the block-diagonal portion of  $\hat{M}$  in the corrector equation (2.12). This results in a decoupling that allows the reuse of M without additional matrix factorizations. However, the products  $(\partial f/\partial y) s_i$  and the vectors  $\partial f/\partial p_i$  must still be reevaluated at each step of the iterative process (2.12) to update the sensitivity portions of the residual  $\hat{G}$ .

#### • Staggered corrector

In this approach [13], as in the staggered direct method, the nonlinear system (2.4) is solved first using the Newton iteration (2.5). Then a separate Newton iteration is used to solve the sensitivity system (2.11):

$$M[s_{i}^{n(m+1)} - s_{i}^{n(m)}] = -\left[s_{i}^{n(m)} - \gamma \left(\frac{\partial f}{\partial y}(t_{n}, y^{n}, p)s_{i}^{n(m)} + \frac{\partial f}{\partial p_{i}}(t_{n}, y^{n}, p)\right) - a_{i,n}\right], \quad (2.13)$$

where  $a_{i,n} = \sum_{j>0} (\alpha_{n,j} s_i^{n-j} + h_n \beta_{n,j} \dot{s}_i^{n-j})$ . In other words, a modified Newton iteration is used to solve a linear system. In this approach, the vectors  $\partial f/\partial p_i$  need be updated only once per integration step, after the state correction phase (2.5) has converged. Note also that Jacobian-related data can be reused at all iterations (2.13) to evaluate the products  $(\partial f/\partial y)s_i$ .

CVODES implements the simultaneous corrector method and two flavors of the staggered corrector method which differ only if the sensitivity variables are included in the error control test. In the full error control case, the first variant of the staggered corrector method requires the convergence of the iterations (2.13) for all  $N_s$  sensitivity systems and then performs the error test on the sensitivity variables. The second variant of the method will perform the error test for each sensitivity vector  $s_i, (i = 1, 2, ..., N_s)$  individually, as they pass the convergence test. Differences in performance between the two variants may therefore be noticed whenever one of the sensitivity vectors  $s_i$  fails a convergence or error test.

An important observation is that the staggered corrector method, combined with a Krylov linear solver, effectively results in a staggered direct method. Indeed, the Krylov solver requires only the action of the matrix M on a vector and this can be provided with the current Jacobian information. Therefore, the modified Newton procedure (2.13) will theoretically converge after one iteration.

#### 2.6.2 Selection of the absolute tolerances for sensitivity variables

If the sensitivities are included in the error test, CVODES provides an automated estimation of absolute tolerances for the sensitivity variables based on the absolute tolerance for the corresponding state variable. The relative tolerance for sensitivity variables is set to be the same as for the state variables. The selection of absolute tolerances for the sensitivity variables is based on the observation that the sensitivity vector  $s_i$  will have units of  $[y]/[p_i]$ . With this, the absolute tolerance for the j-th component of the sensitivity vector  $s_i$  is set to  $ATOL_j/|\bar{p}_i|$ , where  $ATOL_j$  are the absolute tolerances for the state variables and  $\bar{p}$  is a vector of scaling factors that are dimensionally consistent with the model parameters p and give an indication of their order of magnitude. This choice of relative and absolute tolerances is equivalent to requiring that the weighted root-mean-square norm of the sensitivity vector  $s_i$  with weights based on  $s_i$  be the same as the weighted root-mean-square norm of the vector of scaled sensitivities  $\bar{s}_i = |\bar{p}_i| s_i$  with weights based on the state variables (the scaled sensitivities  $\bar{s}_i$  being dimensionally consistent with the state variables). However, this choice of tolerances for the  $s_i$  may be a poor one, and the user of CVODES can provide different values as an option.

#### 2.6.3 Evaluation of the sensitivity right-hand side

There are several methods for evaluating the right-hand side of the sensitivity systems (2.11): analytic evaluation, automatic differentiation, complex-step approximation, and finite differences (or directional derivatives). CVODES provides all the software hooks for implementing interfaces to automatic differentiation (AD) or complex-step approximation; future versions will include a generic interface to AD-generated functions. At the present time, besides the option for analytical sensitivity right-hand sides (user-provided), CVODES can evaluate these quantities using various finite difference-based approximations to evaluate the terms  $(\partial f/\partial y)s_i$  and  $(\partial f/\partial p_i)$ , or using directional derivatives to evaluate  $[(\partial f/\partial y)s_i + (\partial f/\partial p_i)]$ . As is typical for finite differences, the proper choice of perturbations is a delicate matter. CVODES takes into account several problem-related features: the relative ODE error tolerance RTOL, the machine unit roundoff U, the scale factor  $\bar{p}_i$ , and the weighted root-mean-square norm of the sensitivity vector  $s_i$ .

Using central finite differences as an example, the two terms  $(\partial f/\partial y)s_i$  and  $\partial f/\partial p_i$  in the righthand side of (2.11) can be evaluated either separately:

$$\frac{\partial f}{\partial y} s_{i} \approx \frac{f(t, y + \sigma_{y} s_{i}, p) - f(t, y - \sigma_{y} s_{i}, p)}{2 \sigma_{y}}, \qquad (2.14)$$

$$\frac{\partial f}{\partial p_{i}} \approx \frac{f(t, y, p + \sigma_{i} e_{i}) - f(t, y, p - \sigma_{i} e_{i})}{2 \sigma_{i}}, \qquad (2.14')$$

$$\sigma_{i} = |\bar{p}_{i}| \sqrt{\max(\text{RTOL}, U)}, \quad \sigma_{y} = \frac{1}{\max(1/\sigma_{i}, \|s_{i}\|_{\text{WRMS}}/|\bar{p}_{i}|)},$$

$$\frac{\partial f}{\partial p_i} \approx \frac{f(t, y, p + \sigma_i e_i) - f(t, y, p - \sigma_i e_i)}{2 \sigma_i}, \qquad (2.14')$$

$$\sigma_i = |\bar{p}_i| \sqrt{\max(\text{RTOL}, U)}, \quad \sigma_y = \frac{1}{\max(1/\sigma_i, \|s_i\|_{\text{WRMS}}/|\bar{p}_i|)},$$

or simultaneously:

$$\frac{\partial f}{\partial y}s_i + \frac{\partial f}{\partial p_i} \approx \frac{f(t, y + \sigma s_i, p + \sigma e_i) - f(t, y - \sigma s_i, p - \sigma e_i)}{2\sigma}, \qquad (2.15)$$

$$\sigma = \min(\sigma_i, \sigma_y),$$

or by adaptively switching between (2.14)+(2.14) and (2.15), depending on the relative size of the finite difference increments  $\sigma_i$  and  $\sigma_y$ . In the adaptive scheme, if  $\rho = \max(\sigma_i/\sigma_y, \sigma_y/\sigma_i)$ , we use separate evaluations if  $\rho > \rho_{\text{max}}$  (an input value), and simultaneous evaluations otherwise.

These procedures for choosing the perturbations  $(\sigma_i, \sigma_y, \sigma)$  and switching between finite difference and directional derivative formulas have also been implemented for one-sided difference formulas. Forward finite differences can be applied to  $(\partial f/\partial y)s_i$  and  $\partial f/\partial p_i$  separately, or the single directional derivative formula

$$\frac{\partial f}{\partial y}s_i + \frac{\partial f}{\partial p_i} \approx \frac{f(t, y + \sigma s_i, p + \sigma e_i) - f(t, y, p)}{\sigma}$$

can be used. In CVODES, the default value of  $\rho_{\text{max}} = 0$  indicates the use of the second-order centered directional derivative formula (2.15) exclusively. Otherwise, the magnitude of  $\rho_{\text{max}}$  and its sign (positive or negative) indicates whether this switching is done with regard to (centered or forward) finite differences, respectively.

#### 2.6.4 Quadratures depending on forward sensitivities

If pure quadrature variables are also included in the problem definition (see §2.5), CVODES does not carry their sensitivities automatically. Instead, we provide a more general feature through which integrals depending on both the states y of (2.2) and the state sensitivities  $s_i$  of (2.11) can be evaluated. In other words, CVODES provides support for computing integrals of the form:

$$\bar{z}(t) = \int_{t_0}^t \bar{q}(\tau, y(\tau), s_1(\tau), \dots, s_{N_p}(\tau), p) d\tau.$$

If the sensitivities of the quadrature variables z of (2.9) are desired, these can then be computed by using:

$$\bar{q}_i = q_y s_i + q_{p_i}, \quad i = 1, \dots, N_p,$$

as integrands for  $\bar{z}$ , where  $q_y$  and  $q_p$  are the partial derivatives of the integrand function q of (2.9).

As with the quadrature variables z, the new variables  $\bar{z}$  are also excluded from any nonlinear solver phase and "corrected" values  $\bar{z}^n$  are obtained through explicit formulas.

# 2.7 Adjoint sensitivity analysis

In the forward sensitivity approach described in the previous section, obtaining sensitivities with respect to  $N_s$  parameters is roughly equivalent to solving an ODE system of size  $(1 + N_s)N$ . This can become prohibitively expensive, especially for large-scale problems, if sensitivities with respect to many parameters are desired. In this situation, the adjoint sensitivity method is a very attractive alternative, provided that we do not need the solution sensitivities  $s_i$ , but rather the gradients with respect to model parameters of a relatively few derived functionals of the solution. In other words, if y(t) is the solution of (2.2), we wish to evaluate the gradient dG/dp of

$$G(p) = \int_{t_0}^{T} g(t, y, p)dt, \qquad (2.16)$$

or, alternatively, the gradient dg/dp of the function g(t, y, p) at the final time T. The function g must be smooth enough that  $\partial g/\partial y$  and  $\partial g/\partial p$  exist and are bounded.

In what follows, we only sketch the analysis for the sensitivity problem for both G and g. For details on the derivation see [8]. Introducing a Lagrange multiplier  $\lambda$ , we form the augmented objective function

$$I(p) = G(p) - \int_{t_0}^{T} \lambda^* (\dot{y} - f(t, y, p)) dt, \qquad (2.17)$$

where \* denotes the conjugate transpose. The gradient of G with respect to p is

$$\frac{dG}{dp} = \frac{dI}{dp} = \int_{t_0}^{T} (g_p + g_y s) dt - \int_{t_0}^{T} \lambda^* \left( \dot{s} - f_y s - f_p \right) dt, \qquad (2.18)$$

where subscripts on functions f or g are used to denote partial derivatives and  $s = [s_1, \ldots, s_{N_s}]$  is the matrix of solution sensitivities. Applying integration by parts to the term  $\lambda^* \dot{s}$ , and by requiring that  $\lambda$  satisfy

$$\dot{\lambda} = -\left(\frac{\partial f}{\partial y}\right)^* \lambda - \left(\frac{\partial g}{\partial y}\right)^*$$

$$\lambda(T) = 0,$$
(2.19)

the gradient of G with respect to p is nothing but

$$\frac{dG}{dp} = \lambda^*(t_0)s(t_0) + \int_{t_0}^T (g_p + \lambda^* f_p) dt.$$
 (2.20)

The gradient of g(T, y, p) with respect to p can be then obtained by using the Leibnitz differentiation rule. Indeed, from (2.16),

$$\frac{dg}{dp}(T) = \frac{d}{dT}\frac{dG}{dp}$$

and therefore, taking into account that dG/dp in (2.20) depends on T both through the upper integration limit and through  $\lambda$ , and that  $\lambda(T) = 0$ ,

$$\frac{dg}{dp}(T) = \mu^*(t_0)s(t_0) + g_p(T) + \int_{t_0}^T \mu^* f_p dt, \qquad (2.21)$$

where  $\mu$  is the sensitivity of  $\lambda$  with respect to the final integration limit T. Thus  $\mu$  satisfies the following equation, obtained by taking the total derivative with respect to T of (2.19):

$$\dot{\mu} = -\left(\frac{\partial f}{\partial y}\right)^* \mu$$

$$\mu(T) = \left(\frac{\partial g}{\partial y}\right)_{t=T}^*.$$
(2.22)

The final condition on  $\mu(T)$  follows from  $(\partial \lambda/\partial t) + (\partial \lambda/\partial T) = 0$  at T, and therefore,  $\mu(T) = -\dot{\lambda}(T)$ .

The first thing to notice about the adjoint system (2.19) is that there is no explicit specification of the parameters p; this implies that, once the solution  $\lambda$  is found, the formula (2.20) can then be used to find the gradient of G with respect to any of the parameters p. The same holds true for the system (2.22) and the formula (2.21) for gradients of g(T, y, p). The second important remark is that the adjoint systems (2.19) and (2.22) are terminal value problems which depend on the solution y(t) of the original IVP (2.2). Therefore, a procedure is needed for providing the states y obtained during a forward integration phase of (2.2) to CVODES during the backward integration phase of (2.19) or (2.22). The approach adopted in CVODES, based on *checkpointing*, is described below.

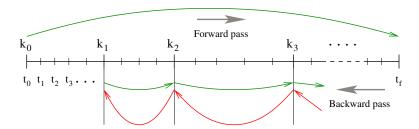

Figure 2.1: Illustration of the checkpointing algorithm for generation of the forward solution during the integration of the adjoint system.

#### 2.7.1 Checkpointing scheme

During the backward integration, the evaluation of the right-hand side of the adjoint system requires, at the current time, the states y which were computed during the forward integration phase. Since CVODES implements variable-step integration formulas, it is unlikely that the states will be available at the desired time and so some form of interpolation is needed. The CVODES implementation being also variable-order, it is possible that during the forward integration phase the order may be reduced as low as first order, which means that there may be points in time where only y and  $\dot{y}$  are available. These requirements therefore limit the choices for possible interpolation schemes. CVODES implements two interpolation methods: a cubic Hermite interpolation algorithm and a variable-degree polynomial interpolation method which attempts to mimic the BDF interpolant for the forward integration.

However, especially for large-scale problems and long integration intervals, the number and size of the vectors y and  $\dot{y}$  that would need to be stored make this approach computationally intractable. Thus, CVODES settles for a compromise between storage space and execution time by implementing a so-called *checkpointing scheme*. At the cost of at most one additional forward integration, this approach offers the best possible estimate of memory requirements for adjoint sensitivity analysis. To begin with, based on the problem size N and the available memory, the user decides on the number  $N_d$  of data pairs  $(y, \dot{y})$  if cubic Hermite interpolation is selected, or on the number  $N_d$  of y vectors in the case of variable-degree polynomial interpolation, that can be kept in memory for the purpose of interpolation. Then, during the first forward integration stage, after every  $N_d$  integration steps a checkpoint is formed by saving enough information (either in memory or on disk) to allow for a hot restart, that is a restart which will exactly reproduce the forward integration. In order to avoid storing Jacobian-related data at each checkpoint, a reevaluation of the iteration matrix is forced before each checkpoint. At the end of this stage, we are left with  $N_c$  checkpoints, including one at  $t_0$ . During the backward integration stage, the adjoint variables are integrated from T to  $t_0$  going from one checkpoint to the previous one. The backward integration from checkpoint i+1 to checkpoint i is preceded by a forward integration from i to i+1 during which the  $N_d$  vectors y (and, if necessary  $\dot{y}$ ) are generated and stored in memory for interpolation (see Fig. 2.1).

This approach transfers the uncertainty in the number of integration steps in the forward integration phase to uncertainty in the final number of checkpoints. However,  $N_c$  is much smaller than the number of steps taken during the forward integration, and there is no major penalty for writing/reading the checkpoint data to/from a temporary file. Note that, at the end of the first forward integration stage, interpolation data are available from the last checkpoint to the end of the interval of integration. If no checkpoints are necessary ( $N_d$  is larger than the number of integration steps taken in the solution of (2.2)), the total cost of an adjoint sensitivity computation can be as low as one

<sup>&</sup>lt;sup>1</sup>The degree of the interpolation polynomial is always that of the current BDF order for the forward interpolation at the first point to the right of the time at which the interpolated value is sought (unless too close to the i-th checkpoint, in which case it uses the BDF order at the right-most relevant point). However, because of the FLC BDF implementation (see §2.1), the resulting interpolation polynomial is only an approximation to the underlying BDF interpolant.

The Hermite cubic interpolation option is present because it was implemented chronologically first and it is also used by other adjoint solvers (e.g. DASPKADJOINT). The variable-degree polynomial is more memory-efficient (it requires only half of the memory storage of the cubic Hermite interpolation) and is more accurate. The accuracy differences are minor when using BDF (since the maximum method order cannot exceed 5), but can be significant for the Adams method for which the order can reach 12.

forward plus one backward integration. In addition, CVODES provides the capability of reusing a set of checkpoints for multiple backward integrations, thus allowing for efficient computation of gradients of several functionals (2.16).

Finally, we note that the adjoint sensitivity module in CVODES provides the necessary infrastructure to integrate backwards in time any ODE terminal value problem dependent on the solution of the IVP (2.2), including adjoint systems (2.19) or (2.22), as well as any other quadrature ODEs that may be needed in evaluating the integrals in (2.20) or (2.21). In particular, for ODE systems arising from semi-discretization of time-dependent PDEs, this feature allows for integration of either the discretized adjoint PDE system or the adjoint of the discretized PDE.

### 2.8 Second-order sensitivity analysis

In some applications (e.g., dynamically-constrained optimization) it may be desirable to compute second-order derivative information. Considering the ODE problem (2.2) and some model output functional, g(y) then the Hessian  $d^2g/dp^2$  can be obtained in a forward sensitivity analysis setting as

$$\frac{d^2g}{dp^2} = (g_y \otimes I_{N_p}) y_{pp} + y_p^T g_{yy} y_p,$$

where  $\otimes$  is the Kronecker product. The second-order sensitivities are solution of the matrix ODE system:

$$\dot{y}_{pp} = \left( f_y \otimes I_{N_p} \right) \cdot y_{pp} + \left( I_N \otimes y_p^T \right) \cdot f_{yy} y_p$$
$$y_{pp}(t_0) = \frac{\partial^2 y_0}{\partial p^2} ,$$

where  $y_p$  is the first-order sensitivity matrix, the solution of  $N_p$  systems (2.11), and  $y_{pp}$  is a third-order tensor. It is easy to see that, except for situations in which the number of parameters  $N_p$  is very small, the computational cost of this so-called *forward-over-forward* approach is exorbitant as it requires the solution of  $N_p + N_p^2$  additional ODE systems of the same dimension N as (2.2).

A much more efficient alternative is to compute Hessian-vector products using a so-called forward-over-adjoint approach. This method is based on using the same "trick" as the one used in computing gradients of pointwise functionals with the adjoint method, namely applying a formal directional forward derivation to one of the gradients of (2.20) or (2.21). With that, the cost of computing a full Hessian is roughly equivalent to the cost of computing the gradient with forward sensitivity analysis. However, Hessian-vector products can be cheaply computed with one additional adjoint solve. Consider for example,  $G(p) = \int_{t_0}^{t_f} g(t, y) dt$ . It can be shown that the product between the Hessian of G (with respect to the parameters p) and some vector u can be computed as

$$\frac{\partial^2 G}{\partial n^2} u = \left[ \left( \lambda^T \otimes I_{N_p} \right) y_{pp} u + y_p^T \mu \right]_{t=t_0},$$

where  $\lambda$ ,  $\mu$ , and s are solutions of

$$-\dot{\mu} = f_y^T \mu + (\lambda^T \otimes I_n) f_{yy} s + g_{yy} s; \quad \mu(t_f) = 0$$

$$-\dot{\lambda} = f_y^T \lambda + g_y^T; \quad \lambda(t_f) = 0$$

$$\dot{s} = f_y s; \quad s(t_0) = y_{0p} u$$

$$(2.23)$$

In the above equation,  $s = y_p u$  is a linear combination of the columns of the sensitivity matrix  $y_p$ . The forward-over-adjoint approach hinges crucially on the fact that s can be computed at the cost of

<sup>&</sup>lt;sup>2</sup>For the sake of simplifity in presentation, we do not include explicit dependencies of g on time t or parameters p. Moreover, we only consider the case in which the dependency of the original ODE (2.2) on the parameters p is through its initial conditions only. For details on the derivation in the general case, see [29].

a forward sensitivity analysis with respect to a single parameter (the last ODE problem above) which is possible due to the linearity of the forward sensitivity equations (2.11).

Therefore, the cost of computing the Hessian-vector product is roughly that of two forward and two backward integrations of a system of ODEs of size N. For more details, including the corresponding formulas for a pointwise model functional output, see [29].

To allow the foward-over-adjoint approach described above, CVODES provides support for:

- the integration of multiple backward problems depending on the same underlying forward problem (2.2), and
- the integration of backward problems and computation of backward quadratures depending on both the states y and forward sensitivities (for this particular application, s) of the original problem (2.2).

# Chapter 3

# **Code Organization**

# 3.1 SUNDIALS organization

The family of solvers referred to as SUNDIALS consists of the solvers CVODE and ARKODE (for ODE systems), KINSOL (for nonlinear algebraic systems), and IDA (for differential-algebraic systems). In addition, SUNDIALS also includes variants of CVODE and IDA with sensitivity analysis capabilities (using either forward or adjoint methods), called CVODES and IDAS, respectively.

The various solvers of this family share many subordinate modules. For this reason, it is organized as a family, with a directory structure that exploits that sharing (see Figs. 3.1 and 3.2). The following is a list of the solver packages presently available, and the basic functionality of each:

- CVODE, a solver for stiff and nonstiff ODE systems dy/dt = f(t, y) based on Adams and BDF methods;
- CVODES, a solver for stiff and nonstiff ODE systems with sensitivity analysis capabilities;
- ARKODE, a solver for ODE systems  $Mdy/dt = f_E(t, y) + f_I(t, y)$  based on additive Runge-Kutta methods;
- IDA, a solver for differential-algebraic systems  $F(t, y, \dot{y}) = 0$  based on BDF methods;
- IDAS, a solver for differential-algebraic systems with sensitivity analysis capabilities;
- KINSOL, a solver for nonlinear algebraic systems F(u) = 0.

# 3.2 CVODES organization

The CVODES package is written in ANSI C. The following summarizes the basic structure of the package, although knowledge of this structure is not necessary for its use.

The overall organization of the CVODES package is shown in Figure 3.3. The basic elements of the structure are a module for the basic integration algorithm (including forward sensitivity analysis), a module for adjoint sensitivity analysis, and support for the solution of linear systems that arise in the case of a stiff system. The central integration module, implemented in the files cvode.h, cvode\_impl.h, and cvode.c, deals with the evaluation of integration coefficients, the functional or Newton iteration process, estimation of local error, selection of stepsize and order, and interpolation to user output points, among other issues. Although this module contains logic for the basic Newton iteration algorithm, it has no knowledge of the method being used to solve the linear systems that arise. For any given user problem, one of the linear system solver interfaces is specified, and is then invoked as needed during the integration.

In addition, if forward sensitivity analysis is turned on, the main module will integrate the forward sensitivity equations simultaneously with the original IVP. The sensitivity variables may be included in the local error control mechanism of the main integrator. CVODES provides three different strategies

30 Code Organization

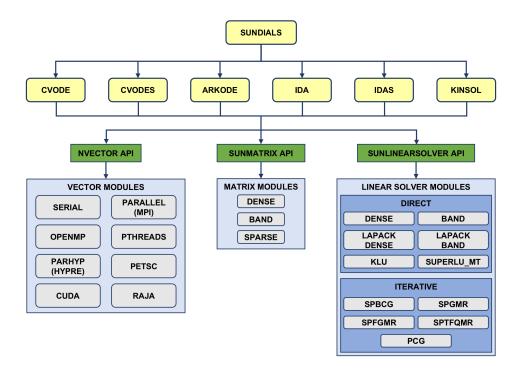

Figure 3.1: High-level diagram of the SUNDIALS suite

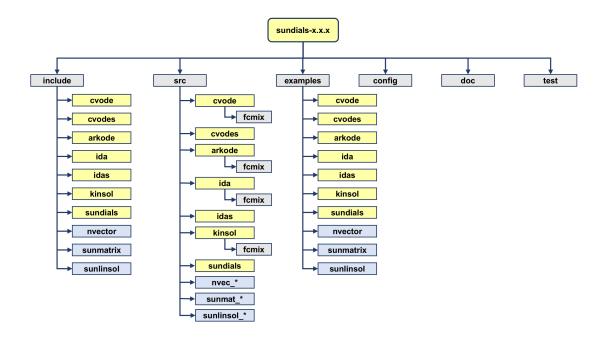

for dealing with the correction stage for the sensitivity variables: CV\_SIMULTANEOUS, CV\_STAGGERED and CV\_STAGGERED1 (see §2.6 and §5.2.1). The CVODES package includes an algorithm for the approximation of the sensitivity equations right-hand sides by difference quotients, but the user has the option of supplying these right-hand sides directly.

The adjoint sensitivity module (file cvodea.c) provides the infrastructure needed for the backward integration of any system of ODEs which depends on the solution of the original IVP, in particular the adjoint system and any quadratures required in evaluating the gradient of the objective functional. This module deals with the setup of the checkpoints, the interpolation of the forward solution during the backward integration, and the backward integration of the adjoint equations.

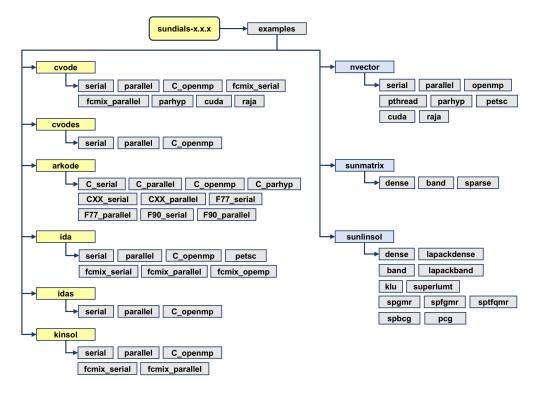

At present, the package includes two linear solver interfaces. The direct linear solver interface, CVDLS, supports SUNLINSOL implementations with type SUNLINSOL\_DIRECT (see Chapter 9). These linear solvers utilize direct methods for the solution of linear systems stored using one of the SUNDIALS generic SUNMATRIX implementations (dense, banded or sparse; see Chapter 8). It is assumed that the dominant cost for such solvers occurs in factorization of the linear system matrix M, so CVODE utilizes these solvers within its modified Newton nonlinear solve. The spils linear solver interface, CVSPILS, supports SUNLINSOL implementations with type SUNLINSOL\_ITERATIVE (see Chapter 9). These linear solvers utilize scaled preconditioned iterative methods. It is assumed that these methods are implemented in a "matrix-free" manner, wherein only the action of the matrix-vector product Mv is required. Since CVODE can operate on any valid SUNLINSOL implementation of SUNLINSOL\_DIRECT or SUNLINSOL\_ITERATIVE types, the set of linear solver modules available to CVODES will expand as new SUNLINSOL modules are developed.

Additionally, CVODES includes the *diagonal* linear solver interface, CVDIAG, that creates an internally generated diagonal approximation to the Jacobian.

Within the CVDLS interface, the package includes algorithms for the approximation of dense or banded Jacobians through difference quotients, but the user also has the option of supplying the Jacobian (or an approximation to it) directly. This user-supplied routine is required when using sparse Jacobian matrices, since standard difference quotient approximations do not leverage the inherent

(b) Directory structure of the Sundials examples

Figure 3.2: Organization of the SUNDIALS suite

32 Code Organization

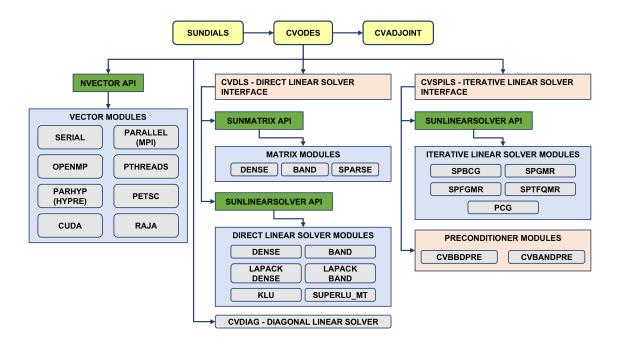

Figure 3.3: Overall structure of the CVODES package. Modules specific to CVODES begin with "CV" (CVDLS, CVDIAG, CVSPILS, CVBBDPRE and CVBANDPRE), all other items correspond to generic solver and auxiliary modules. Note also that the LAPACK, KLU and SUPERLUMT support is through interfaces to external packages. Users will need to download and compile those packages independently.

sparsity of the problem.

Within the CVSPILS interface, the package includes an algorithm for the approximation by difference quotients of the product Mv. Again, the user has the option of providing routines for this operation, in two phases: setup (preprocessing of Jacobian data) and multiplication. For preconditioned iterative methods, the preconditioning must be supplied by the user, again in two phases: setup and solve. While there is no default choice of preconditioner analogous to the difference-quotient approximation in the direct case, the references [4, 5], together with the example and demonstration programs included with CVODES, offer considerable assistance in building preconditioners.

Each CVODE linear solver interface consists of four primary phases, devoted to (1) memory allocation and initialization, (2) setup of the matrix data involved, (3) solution of the system, and (4) freeing of memory. The setup and solution phases are separate because the evaluation of Jacobians and preconditioners is done only periodically during the integration, and only as required to achieve convergence.

CVODES also provides two preconditioner modules, for use with any of the Krylov iterative linear solvers. The first one, CVBANDPRE, is intended to be used with NVECTOR\_SERIAL, NVECTOR\_OPENMP or NVECTOR\_PTHREADS and provides a banded difference-quotient Jacobian-based preconditioner, with corresponding setup and solve routines. The second preconditioner module, CVBBDPRE, works in conjunction with NVECTOR\_PARALLEL and generates a preconditioner that is a block-diagonal matrix with each block being a banded matrix.

All state information used by CVODES to solve a given problem is saved in a structure, and a pointer to that structure is returned to the user. There is no global data in the CVODES package, and so, in this respect, it is reentrant. State information specific to the linear solver is saved in a separate structure, a pointer to which resides in the CVODES memory structure. The reentrancy of CVODES was motivated by the anticipated multicomputer extension, but is also essential in a uniprocessor setting where two or more problems are solved by intermixed calls to the package from within a single user program.

# Chapter 4

# Using CVODES for IVP Solution

This chapter is concerned with the use of CVODES for the solution of initial value problems (IVPs). The following sections treat the header files and the layout of the user's main program, and provide descriptions of the CVODES user-callable functions and user-supplied functions. This usage is essentially equivalent to using CVODE [21].

The sample programs described in the companion document [35] may also be helpful. Those codes may be used as templates (with the removal of some lines used in testing) and are included in the CVODES package.

The user should be aware that not all SUNLINSOL and SUNMATRIX modules are compatible with all NVECTOR implementations. Details on compatability are given in the documentation for each SUNMATRIX module (Chapter 8) and each SUNLINSOL module (Chapter 9). For example, NVECTOR\_PARALLEL is not compatible with the dense, banded, or sparse SUNMATRIX types, or with the corresponding dense, banded, or sparse SUNLINSOL modules. Please check Chapters 8 and 9 to verify compatability between these modules. In addition to that documentation, we note that the CVBAND-PRE preconditioning module is only compatible with the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector implementations, and the preconditioner module CVBBDPRE can only be used with NVECTOR\_PARALLEL. It is not recommended to use a threaded vector module with SuperLU\_MT unless it is the NVECTOR\_OPENMP module, and SuperLU\_MT is also compiled with openMP.

CVODES uses various constants for both input and output. These are defined as needed in this chapter, but for convenience are also listed separately in Appendix B.

# 4.1 Access to library and header files

At this point, it is assumed that the installation of CVODES, following the procedure described in Appendix A, has been completed successfully.

Regardless of where the user's application program resides, its associated compilation and load commands must make reference to the appropriate locations for the library and header files required by CVODES. The relevant library files are

- libdir/libsundials\_cvodes.lib,
- libdir/libsundials\_nvec\*. lib (one to four files),

where the file extension .lib is typically .so for shared libraries and .a for static libraries. The relevant header files are located in the subdirectories

- incdir/include/cvodes
- incdir/include/sundials
- incdir/include/nvector

- incdir/include/sunmatrix
- *incdir*/include/sunlinsol

The directories *libdir* and *incdir* are the install library and include directories, respectively. For a default installation, these are *instdir*/lib and *instdir*/include, respectively, where *instdir* is the directory where SUNDIALS was installed (see Appendix A).

Note that an application cannot link to both the CVODE and CVODES libraries because both contain user-callable functions with the same names (to ensure that CVODES is backward compatible with CVODE). Therefore, applications that contain both ODE problems and ODEs with sensitivity analysis, should use CVODES.

# 4.2 Data Types

The sundials\_types.h file contains the definition of the type realtype, which is used by the SUNDIALS solvers for all floating-point data, the definition of the integer type sunindextype, which is used for vector and matrix indices, and booleantype, which is used for certain logic operations within SUNDIALS.

# 4.2.1 Floating point types

The type realtype can be float, double, or long double, with the default being double. The user can change the precision of the SUNDIALS solvers arithmetic at the configuration stage (see §A.1.2).

Additionally, based on the current precision, sundials\_types.h defines BIG\_REAL to be the largest value representable as a realtype, SMALL\_REAL to be the smallest value representable as a realtype, and UNIT\_ROUNDOFF to be the difference between 1.0 and the minimum realtype greater than 1.0.

Within SUNDIALS, real constants are set by way of a macro called RCONST. It is this macro that needs the ability to branch on the definition realtype. In ANSI C, a floating-point constant with no suffix is stored as a double. Placing the suffix "F" at the end of a floating point constant makes it a float, whereas using the suffix "L" makes it a long double. For example,

```
#define A 1.0
#define B 1.0F
#define C 1.0L
```

defines A to be a double constant equal to 1.0, B to be a float constant equal to 1.0, and C to be a long double constant equal to 1.0. The macro call RCONST(1.0) automatically expands to 1.0 if realtype is double, to 1.0F if realtype is float, or to 1.0L if realtype is long double. SUNDIALS uses the RCONST macro internally to declare all of its floating-point constants.

A user program which uses the type realtype and the RCONST macro to handle floating-point constants is precision-independent except for any calls to precision-specific standard math library functions. (Our example programs use both realtype and RCONST.) Users can, however, use the type double, float, or long double in their code (assuming that this usage is consistent with the typedef for realtype). Thus, a previously existing piece of ANSI C code can use SUNDIALS without modifying the code to use realtype, so long as the SUNDIALS libraries use the correct precision (for details see  $\S A.1.2$ ).

### 4.2.2 Integer types used for vector and matrix indices

The type sunindextype can be either a 32- or 64-bit signed integer. The default is the portable int64\_t type, and the user can change it to int32\_t at the configuration stage. The configuration system will detect if the compiler does not support portable types, and will replace int32\_t and int64\_t with int and long int, respectively, to ensure use of the desired sizes on Linux, Mac OS X, and Windows platforms. SUNDIALS currently does not support unsigned integer types for vector and matrix indices, although these could be added in the future if there is sufficient demand.

4.3 Header files 37

A user program which uses sunindextype to handle vector and matrix indices will work with both index storage types except for any calls to index storage-specific external libraries. (Our C and C++ example programs use sunindextype.) Users can, however, use any one of int, long int, int32\_t, int64\_t or long long int in their code, assuming that this usage is consistent with the typedef for sunindextype on their architecture). Thus, a previously existing piece of ANSI C code can use SUNDIALS without modifying the code to use sunindextype, so long as the SUNDIALS libraries use the appropriate index storage type (for details see §A.1.2).

### 4.3 Header files

The calling program must include several header files so that various macros and data types can be used. The header file that is always required is:

• cvodes.h, the main header file for CVODES, which defines the several types and various constants, and includes function prototypes.

Note that cvodes.h includes sundials\_types.h, which defines the types realtype, sunindextype, and booleantype and the constants SUNFALSE and SUNTRUE.

The calling program must also include an NVECTOR implementation header file, of the form nvector/nvector\_\*\*\*.h. See Chapter 7 for the appropriate name. This file in turn includes the header file sundials\_nvector.h which defines the abstract N\_Vector data type.

If the user chooses Newton iteration for the solution of the nonlinear systems, then a linear solver module header file will be required. The header files corresponding to the various linear solver interfaces and linear solver modules available for use with CVODES are:

- cvodes\_cvodes\_direct.h, which is used with the CVDLS direct linear solver interface to access direct solvers with the following header files:
  - sunlinsol/sunlinsol\_dense.h, which is used with the dense linear solver module, SUN-LINSOL\_DENSE;
  - sunlinsol/sunlinsol\_band.h, which is used with the banded linear solver module, SUN-LINSOL\_BAND;
  - sunlinsol/sunlinsol\_lapackdense.h, which is used with the LAPACK dense linear solver interface module, SUNLINSOL\_LAPACKDENSE;
  - sunlinsol/sunlinsol\_lapackband.h, which is used with the LAPACK banded linear solver interface module, SUNLINSOL\_LAPACKBAND;
  - sunlinsol/sunlinsol\_klu.h, which is used with the KLU sparse linear solver interface module, SUNLINSOL\_KLU;
  - sunlinsol/sunlinsol\_superlumt.h, which is used with the SUPERLUMT sparse linear solver interface module, SUNLINSOL\_SUPERLUMT;
- cvodes/cvodes\_spils.h, which is used with the CVSPILS iterative linear solver interface to access iterative solvers with the following header files:
  - sunlinsol/sunlinsol\_spgmr.h, which is used with the scaled, preconditioned GMRES Krylov linear solver module, SUNLINSOL\_SPGMR;
  - sunlinsol/sunlinsol\_spfgmr.h, which is used with the scaled, preconditioned FGMRES Krylov linear solver module, SUNLINSOL\_SPFGMR;
  - sunlinsol/sunlinsol\_spbcgs.h, which is used with the scaled, preconditioned Bi-CGStab Krylov linear solver module, SUNLINSOL\_SPBCGS;
  - sunlinsol/sunlinsol\_sptfqmr.h, which is used with the scaled, preconditioned TFQMR
     Krylov linear solver module, SUNLINSOL\_SPTFQMR;

- sunlinsol/sunlinsol\_pcg.h, which is used with the scaled, preconditioned CG Krylov linear solver module, SUNLINSOL\_PCG;
- cvodes/cvodes\_diag.h, which is used with the CVDIAG diagonal linear solver interface.

The header files for the SUNLINSOL\_DENSE and SUNLINSOL\_LAPACKDENSE linear solver modules include the file sunmatrix/sunmatrix\_dense.h, which defines the SUNMATRIX\_DENSE matrix module, as as well as various functions and macros acting on such matrices.

The header files for the SUNLINSOL\_BAND and SUNLINSOL\_LAPACKBAND linear solver modules include the file sunmatrix/sunmatrix\_band.h, which defines the SUNMATRIX\_BAND matrix module, as as well as various functions and macros acting on such matrices.

The header files for the SUNLINSOL\_KLU and SUNLINSOL\_SUPERLUMT sparse linear solvers include the file sunmatrix\_sparse.h, which defines the SUNMATRIX\_SPARSE matrix module, as well as various functions and macros acting on such matrices.

The header files for the Krylov iterative solvers include the file sundials\_iterative.h, which enumerates the kind of preconditioning, and (for the SPGMR and SPFGMR solvers) the choices for the Gram-Schmidt process.

Other headers may be needed, according to the choice of preconditioner, etc. For example, in the cvsDiurnal\_kry\_p example (see [35]), preconditioning is done with a block-diagonal matrix. For this, even though the SUNLINSOL\_SPGMR linear solver is used, the header sundials/sundials\_dense.h is included for access to the underlying generic dense matrix arithmetic routines.

# 4.4 A skeleton of the user's main program

The following is a skeleton of the user's main program (or calling program) for the integration of an ODE IVP. Most of the steps are independent of the NVECTOR, SUNMATRIX, and SUNLINSOL implementations used. For the steps that are not, refer to Chapters 7, 8, and 9 for the specific name of the function to be called or macro to be referenced.

### 1. Initialize parallel or multi-threaded environment, if appropriate

For example, call MPI\_Init to initialize MPI if used, or set num\_threads, the number of threads to use within the threaded vector functions, if used.

### 2. Set problem dimensions etc.

This generally includes the problem size N, and may include the local vector length Nlocal.

Note: The variables N and Nlocal should be of type sunindextype.

#### 3. Set vector of initial values

To set the vector y0 of initial values, use the appropriate functions defined by the particular NVECTOR implementation.

For native SUNDIALS vector implementations (except the CUDA and RAJA-based ones), use a call of the form  $y0 = N_VMake_***(..., ydata)$  if the realtype array ydata containing the initial values of y already exists. Otherwise, create a new vector by making a call of the form  $y0 = N_VMew_***(...)$ , and then set its elements by accessing the underlying data with a call of the form ydata =  $N_VGetArrayPointer(y0)$ . See §7.1-7.4 for details.

For the hypre and PETSc vector wrappers, first create and initialize the underlying vector, and then create an NVECTOR wrapper with a call of the form y0 = N\_VMake\_\*\*\*(yvec), where yvec is a hypre or PETSc vector. Note that calls like N\_VNew\_\*\*\*(...) and N\_VGetArrayPointer(...) are not available for these vector wrappers. See §7.5 and §7.6 for details.

If using either the CUDA- or RAJA-based vector implementations use a call of the form y0 = N\_VMake\_\*\*\*(..., c) where c is a pointer to a suncudavec or sunrajavec vector class if this class already exists. Otherwise, create a new vector by making a call of the form y0 = N\_VNew\_\*\*\*(...),

and then set its elements by accessing the underlying data where it is located with a call of the form N\_VGetDeviceArrayPointer\_\*\*\*. Note that the vector class will allocate memory on both the host and device when instantiated. See §7.7-7.8 for details.

### 4. Create CVODES object

Call cvode\_mem = CVodeCreate(lmm, iter) to create the CVODES memory block and to specify the solution method (linear multistep method and nonlinear solver iteration type). CVodeCreate returns a pointer to the CVODES memory structure. See §4.5.1 for details.

#### 5. Initialize CVODES solver

Call CVodeInit(...) to provide required problem specifications, allocate internal memory for CVODES, and initialize CVODES. CVodeInit returns a flag, the value of which indicates either success or an illegal argument value. See §4.5.1 for details.

### 6. Specify integration tolerances

Call CVodeSStolerances(...) or CVodeSVtolerances(...) to specify either a scalar relative tolerance and scalar absolute tolerance, or a scalar relative tolerance and a vector of absolute tolerances, respectively. Alternatively, call CVodeWFtolerances to specify a function which sets directly the weights used in evaluating WRMS vector norms. See §4.5.2 for details.

### 7. Set optional inputs

Call CVodeSet\* functions to change any optional inputs that control the behavior of CVODES from their default values. See §4.5.6.1 for details.

### 8. Create matrix object

If a direct linear solver is to be used within a Newton iteration then a template Jacobian matrix must be created by using the appropriate functions defined by the particular SUNMATRIX implementation.

NOTE: The dense, banded, and sparse matrix objects are usable only in a serial or threaded environment.

### 9. Create linear solver object

If a Newton iteration is chosen, then the desired linear solver object must be created by using the appropriate functions defined by the particular SUNLINSOL implementation.

### 10. Set linear solver optional inputs

Call \*Set\* functions from the selected linear solver module to change optional inputs specific to that linear solver. See the documentation for each SUNLINSOL module in Chapter 9 for details.

### 11. Attach linear solver module

If a Newton iteration is chosen, initialize the CVDLS or CVSPILS linear solver interface by attaching the linear solver object (and matrix object, if applicable) with one of the following calls (for details see §4.5.3):

```
ier = CVDlsSetLinearSolver(...);
ier = CVSpilsSetLinearSolver(...);
```

Alternately, if the CVODES-specific diagonal linear solver module, CVDIAG, is desired, initialize the linear solver module and attach it to CVODES with the call

```
ier = CVDiag(...);
```

### 12. Set linear solver interface optional inputs

Call CVDlsSet\* or CVSpilsSet\* functions to change optional inputs specific to that linear solver interface. See §4.5.6 for details.

### 13. Specify rootfinding problem

Optionally, call CVodeRootInit to initialize a rootfinding problem to be solved during the integration of the ODE system. See §4.5.4, and see §4.5.6.4 for relevant optional input calls.

#### 14. Advance solution in time

For each point at which output is desired, call ier = CVode(cvode\_mem, tout, yout, &tret, itask). Here itask specifies the return mode. The vector yout (which can be the same as the vector y0 above) will contain y(t). See §4.5.5 for details.

### 15. Get optional outputs

Call CV\*Get\* functions to obtain optional output. See §4.5.8 for details.

### 16. Deallocate memory for solution vector

Upon completion of the integration, deallocate memory for the vector y (or yout) by calling the appropriate destructor function defined by the NVECTOR implementation:

N\_VDestroy(y);

### 17. Free solver memory

Call CVodeFree (&cvode\_mem) to free the memory allocated by CVODES.

### 18. Free linear solver and matrix memory

Call SUNLinSolFree and SUNMatDestroy to free any memory allocated for the linear solver and matrix objects created above.

### 19. Finalize MPI, if used

Call MPI\_Finalize() to terminate MPI.

SUNDIALS provides some linear solvers only as a means for users to get problems running and not as highly efficient solvers. For example, if solving a dense system, we suggest using the Lapack solvers if the size of the linear system is > 50,000. (Thanks to A. Nicolai for his testing and recommendation.) Table 4.1 shows the linear solver interfaces available as SUNLINSOL modules and the vector implementations required for use. As an example, one cannot use the dense direct solver interfaces with the MPI-based vector implementation. However, as discussed in Chapter 9 the SUNDIALS packages operate on generic SUNLINSOL objects, allowing a user to develop their own solvers should they so desire.

### 4.5 User-callable functions

This section describes the CVODES functions that are called by the user to setup and then solve an IVP. Some of these are required. However, starting with  $\S4.5.6$ , the functions listed involve optional inputs/outputs or restarting, and those paragraphs may be skipped for a casual use of CVODES. In any case, refer to  $\S4.4$  for the correct order of these calls.

On an error, each user-callable function returns a negative value and sends an error message to the error handler routine, which prints the message on **stderr** by default. However, the user can set a file as error output or can provide his own error handler function (see §4.5.6.1).

# 4.5.1 CVODES initialization and deallocation functions

The following three functions must be called in the order listed. The last one is to be called only after the IVP solution is complete, as it frees the CVODES memory block created and allocated by the first

Linear Solver	Serial	Parallel (MPI)	OpenMP	pThreads	hypre	PETSC	CUDA	RAJA	User Supp.
Dense	<b>√</b>		<b>√</b>	<b>√</b>					✓
Band	<b>√</b>		<b>√</b>	<b>√</b>					✓
LapackDense	<b>√</b>		<b>√</b>	<b>√</b>					✓
LapackBand	<b>√</b>		<b>√</b>	<b>√</b>					✓
KLU	<b>√</b>		<b>√</b>	<b>√</b>					✓
SUPERLUMT	<b>√</b>		<b>√</b>	<b>√</b>					✓
SPGMR	<b>√</b>	✓	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	✓

SPTFQMR	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	✓
PCG	<b>√</b>	✓	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	✓
User Supp.	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>	<b>√</b>

Table 4.1: SUNDIALS linear solver interfaces and vector implementations that can be used for each.

two calls.

### CVodeCreate

Description The function CVodeCreate instantiates a CVODES solver object and specifies the solution method.

Arguments lmm (int) specifies the linear multistep method and may be one of two possible values: CV\_ADAMS or CV\_BDF.

iter (int) specifies the type of nonlinear solver iteration and may be either CV\_NEWTON
 or CV\_FUNCTIONAL.

The recommended choices for (lmm, iter) are (CV\_ADAMS, CV\_FUNCTIONAL) for nonstiff problems and (CV\_BDF, CV\_NEWTON) for stiff problems.

Return value If successful, CVodeCreate returns a pointer to the newly created CVODES memory block (of type void \*). Otherwise, it returns NULL.

### CVodeInit

Call flag = CVodeInit(cvode\_mem, f, t0, y0);

Description The function CVodeInit provides required problem and solution specifications, allocates internal memory, and initializes CVODES.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

f (CVRhsFn) is the C function which computes the right-hand side function f in the ODE. This function has the form f(t, y, ydot, user\_data) (for full details see §4.6.1).

to (realtype) is the initial value of t.

y0 (N\_Vector) is the initial value of y.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeInit was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_MEM\_FAIL A memory allocation request has failed.

CV\_ILL\_INPUT An input argument to CVodeInit has an illegal value.

Notes

If an error occurred, CVodeInit also sends an error message to the error handler function.

### CVodeFree

Call CVodeFree(&cvode\_mem);

The function CVodeFree frees the memory allocated by a previous call to CVodeCreate. Description

Arguments The argument is the pointer to the CVODES memory block (of type void \*).

Return value The function CVodeFree has no return value.

#### 4.5.2CVODES tolerance specification functions

One of the following three functions must be called to specify the integration tolerances (or directly specify the weights used in evaluating WRMS vector norms). Note that this call must be made after the call to CVodeInit.

### CVodeSStolerances

Call flag = CVodeSStolerances(cvode\_mem, reltol, abstol);

Description The function CVodeSStolerances specifies scalar relative and absolute tolerances.

cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate. Arguments

> reltol (realtype) is the scalar relative error tolerance. (realtype) is the scalar absolute error tolerance. abstol

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSStolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call

to CVodeCreate.

CV\_NO\_MALLOC The allocation function CVodeInit has not been called.

CV\_ILL\_INPUT One of the input tolerances was negative.

### CVodeSVtolerances

Call flag = CVodeSVtolerances(cvode\_mem, reltol, abstol);

Description The function CVodeSVtolerances specifies scalar relative tolerance and vector absolute

tolerances.

cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate. Arguments

> reltol (realtype) is the scalar relative error tolerance.

abstol (N\_Vector) is the vector of absolute error tolerances.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSVtolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_NO\_MALLOC The allocation function CVodeInit has not been called.

CV\_ILL\_INPUT The relative error tolerance was negative or the absolute tolerance had a negative component.

Notes This choice of tolerances is important when the absolute error tolerance needs to be different for each component of the state vector y.

### CVodeWFtolerances

Call flag = CVodeWFtolerances(cvode\_mem, efun);

The function CVodeWFtolerances specifies a user-supplied function efun that sets the Description

multiplicative error weights  $W_i$  for use in the weighted RMS norm, which are normally

defined by Eq. (2.7).

cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate. Arguments

(CVEwtFn) is the C function which defines the ewt vector (see §4.6.3).

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeWFtolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_NO\_MALLOC The allocation function CVodeInit has not been called.

General advice on choice of tolerances. For many users, the appropriate choices for tolerance values in reltol and abstol are a concern. The following pieces of advice are relevant.

- (1) The scalar relative tolerance reltol is to be set to control relative errors. So reltol =  $10^{-4}$ means that errors are controlled to .01%. We do not recommend using reltol larger than  $10^{-3}$ . On the other hand, reltol should not be so small that it is comparable to the unit roundoff of the machine arithmetic (generally around 1.0E-15).
- (2) The absolute tolerances abstol (whether scalar or vector) need to be set to control absolute errors when any components of the solution vector y may be so small that pure relative error control is meaningless. For example, if y[i] starts at some nonzero value, but in time decays to zero, then pure relative error control on y[i] makes no sense (and is overly costly) after y[i] is below some noise level. Then abstol (if scalar) or abstol[i] (if a vector) needs to be set to that noise level. If the different components have different noise levels, then abstol should be a vector. See the example cvsRoberts\_dns in the CVODES package, and the discussion of it in the CVODES Examples document [35]. In that problem, the three components vary betwee 0 and 1, and have different noise levels; hence the abstol vector. It is impossible to give any general advice on abstol values, because the appropriate noise levels are completely problem-dependent. The user or modeler hopefully has some idea as to what those noise levels are.
- (3) Finally, it is important to pick all the tolerance values conservatively, because they control the error committed on each individual time step. The final (global) errors are some sort of accumulation of those per-step errors. A good rule of thumb is to reduce the tolerances by a factor of .01 from the actual desired limits on errors. So if you want .01% accuracy (globally), a good choice is reltol  $=10^{-6}$ . But in any case, it is a good idea to do a few experiments with the tolerances to see how the computed solution values vary as tolerances are reduced.

Advice on controlling unphysical negative values. In many applications, some components in the true solution are always positive or non-negative, though at times very small. In the numerical solution, however, small negative (hence unphysical) values can then occur. In most cases, these values are harmless, and simply need to be controlled, not eliminated. The following pieces of advice are

- (1) The way to control the size of unwanted negative computed values is with tighter absolute tolerances. Again this requires some knowledge of the noise level of these components, which may or may not be different for different components. Some experimentation may be needed.
- (2) If output plots or tables are being generated, and it is important to avoid having negative numbers appear there (for the sake of avoiding a long explanation of them, if nothing else), then eliminate them, but only in the context of the output medium. Then the internal values carried by the solver are unaffected. Remember that a small negative value in y returned by CVODES, with magnitude comparable to abstol or less, is equivalent to zero as far as the computation is concerned.
- (3) The user's right-hand side routine f should never change a negative value in the solution vector y to a non-negative value, as a "solution" to this problem. This can cause instability. If the f routine cannot tolerate a zero or negative value (e.g. because there is a square root or log of it), then the

offending value should be changed to zero or a tiny positive number in a temporary variable (not in the input y vector) for the purposes of computing f(t, y).

(4) Positivity and non-negativity constraints on components can be enforced by use of the recoverable error return feature in the user-supplied right-hand side function. However, because this option involves some extra overhead cost, it should only be exercised if the use of absolute tolerances to control the computed values is unsuccessful.

### 4.5.3 Linear solver interface functions

As previously explained, a Newton iteration requires the solution of linear systems of the form (2.5). There are three CVODES linear solver interfaces currently available for this task: CVDLS, CVDIAG and CVSPILS

The first corresponds to the use of Direct Linear Solvers, and utilizes SUNMATRIX objects to store the Jacobian  $J = \partial f/\partial y$ , the Newton matrix  $M = I - \gamma J$ , and factorizations used throughout the solution process.

The CVDIAG linear solver is also a direct linear solver, but it only uses a diagonal approximation to J.

The third corresponds to the use of Scaled, Preconditioned, Iterative Linear Solvers, utilizing matrix-free Krylov methods to solve the Newton linear systems of equations. With most of these methods, preconditioning can be done on the left only, on the right only, on both the left and the right, or not at all. The exceptions to this rule are SPFGMR that supports right preconditioning only and PCG that performs symmetric preconditioning. For the specification of a preconditioner, see the iterative linear solver sections in §4.5.6 and §4.6.

If preconditioning is done, user-supplied functions define left and right preconditioner matrices  $P_1$  and  $P_2$  (either of which could be the identity matrix), such that the product  $P_1P_2$  approximates the Newton matrix  $M = I - \gamma J$  of (2.6).

To specify a generic linear solver to CVODES, after the call to CVodeCreate but before any calls to CVodes, the user's program must create the appropriate SUNLINSOL object and call either of the functions CVDlsSetLinearSolver or CVSpilsSetLinearSolver, as documented below. The first argument passed to these functions is the CVODES memory pointer returned by CVodeCreate; the second argument passed to these functions is the desired SUNLINSOL object to use for solving Newton systems. A call to one of these functions initializes the appropriate CVODES linear solver interface, linking this to the main CVODES integrator, and allows the user to specify parameters which are specific to a particular solver interface. The use of each of the generic linear solvers involves certain constants and possibly some macros, that are likely to be needed in the user code. These are available in the corresponding header file associated with the specific SUNMATRIX or SUNLINSOL module in question, as described in Chapters 8 and 9.

To instead specify the CVODES-specific diagonal linear solver interface, the user's program must call CVDiag, as documented below. The first argument passed to this function is the CVODES memory pointer returned by CVodeCreate.

### CVDlsSetLinearSolver

Call flag = CVDlsSetLinearSolver(cvode\_mem, LS, J);

Description The function CVDlsSetLinearSolver attaches a direct SUNLINSOL object LS and corresponding template Jacobian SUNMATRIX object J to CVODES, initializing the CVDLS direct linear solver interface.

The user's main program must include the cvodes\_direct.h header file.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

LS (SUNLinearSolver) SUNLINSOL object to use for solving Newton linear systems.

J (SUNMatrix) SUNMATRIX object for used as a template for the Jacobian (must have a type compatible with the linear solver object).

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The CVDLS initialization was successful.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_ILL\_INPUT The CVDLS solver is not compatible with the LS or J input objects or is incompatible with the current NVECTOR module.

CVDLS\_MEM\_FAIL A memory allocation request failed.

Notes

The CVDLS linear solver interface is not compatible with all implementations of the SUN-LINSOL and NVECTOR modules. Specifically, CVDLS requires use of a *direct* SUNLINSOL object and a serial or theaded NVECTOR module. Additional compatibility limitations for each SUNLINSOL object (i.e. SUNMATRIX and NVECTOR object compatibility) are described in Chapter 9.

### CVSpilsSetLinearSolver

Call flag = CVSpilsSetLinearSolver(cvode\_mem, LS);

Description The function CVSpilsSetLinearSolver attaches an iterative SUNLINSOL object LS to

CVODES, initializing the CVSPILS scaled, preconditioned, iterative linear solver interface.

The user's main program must include the cvodes\_spils.h header file.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

LS (SUNLinearSolver) SUNLINSOL object to use for solving Newton linear sys-

tems.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The CVSPILS initialization was successful.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_ILL\_INPUT The CVSPILS solver is not compatible with the LS object or is incompatible with the current NVECTOR module.

CVSPILS\_MEM\_FAIL A memory allocation request failed.

CVSPILS\_SUNLS\_FAIL A call to the LS object failed.

Notes

The CVSPILS linear solver interface is not compatible with all implementations of the SUNLINSOL and NVECTOR modules. Specifically, CVSPILS requires use of an *iterative* SUNLINSOL object. Additional compatibility limitations for each SUNLINSOL object (i.e. required NVECTOR routines) are described in Chapter 9.

# ${\tt CVDiag}$

Call flag = CVDiag(cvode\_mem);

Description The function CVDiag selects the CVDIAG linear solver.

The user's main program must include the cvodes\_diag.h header file.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

Return value The return value flag (of type int) is one of:

CVDIAG\_SUCCESS The CVDIAG initialization was successful.

CVDIAG\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDIAG\_ILL\_INPUT The CVDIAG solver is not compatible with the current NVECTOR

module.

CVDIAG\_MEM\_FAIL A memory allocation request failed.

Notes

The CVDIAG solver is the simplest of all of the current CVODES linear solver interfaces. The CVDIAG solver uses an approximate diagonal Jacobian formed by way of a difference quotient. The user does *not* have the option of supplying a function to compute an approximate diagonal Jacobian.

### 4.5.4 Rootfinding initialization function

While solving the IVP, CVODES has the capability to find the roots of a set of user-defined functions. To activate the root finding algorithm, call the following function. This is normally called only once, prior to the first call to CVode, but if the rootfinding problem is to be changed during the solution, CVodeRootInit can also be called prior to a continuation call to CVode.

### ${\tt CVodeRootInit}$

Call flag = CVodeRootInit(cvode\_mem, nrtfn, g);

Description The function CVodeRootInit specifies that the roots of a set of functions  $g_i(t,y)$  are to

be found while the IVP is being solved.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

**nrtfn** (int) is the number of root functions  $g_i$ .

g (CVRootFn) is the C function which defines the nrtfn functions  $g_i(t,y)$ 

whose roots are sought. See  $\S4.6.4$  for details.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The call to CVodeRootInit was successful.

CV\_MEM\_NULL The cvode\_mem argument was NULL.

CV\_MEM\_FAIL A memory allocation failed.

CV\_ILL\_INPUT The function g is NULL, but nrtfn > 0.

Notes If a new IVP is to be solved with a call to CVodeReInit, where the new IVP has no rootfinding problem but the prior one did, then call CVodeRootInit with nrtfn= 0.

### 4.5.5 CVODES solver function

This is the central step in the solution process — the call to perform the integration of the IVP. One of the input arguments (itask) specifies one of two modes as to where CVODES is to return a solution. But these modes are modified if the user has set a stop time (with CVodeSetStopTime) or requested rootfinding.

### CVode

Call flag = CVode(cvode\_mem, tout, yout, &tret, itask);

Description The function CVode integrates the ODE over an interval in t.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

tout (realtype) the next time at which a computed solution is desired.

yout (N\_Vector) the computed solution vector.

tret (realtype) the time reached by the solver (output).

itask (int) a flag indicating the job of the solver for the next user step. The CV\_NORMAL option causes the solver to take internal steps until it has reached or just passed the user-specified tout parameter. The solver then interpolates in order to return an approximate value of y(tout). The CV\_ONE\_STEP option tells the solver to take just one internal step and then return the

solution at the point reached by that step.

Return value CVode returns a vector yout and a corresponding independent variable value t = tret, such that yout is the computed value of y(t).

In CV\_NORMAL mode (with no errors), tret will be equal to tout and yout = y(tout).

The return value flag (of type int) will be one of the following:

CV\_SUCCESS CVode succeeded and no roots were found.

CV\_ROOT\_RETURN

CV\_TSTOP\_RETURN CVode succeeded by reaching the stopping point specified through the optional input function CVodeSetStopTime (see §4.5.6.1).

CVode succeeded and found one or more roots. In this case, tret is

the location of the root. If nrtfn > 1, call CVodeGetRootInfo to

see which  $g_i$  were found to have a root.

 ${\tt CV\_MEM\_NULL} \qquad \qquad {\tt The \ cvode\_mem \ argument \ was \ NULL}.$ 

CV\_NO\_MALLOC The CVODES memory was not allocated by a call to CVodeInit.

CV\_ILL\_INPUT One of the inputs to CVode was illegal, or some other input to the

solver was either illegal or missing. The latter category includes the following situations: (a) The tolerances have not been set. (b) A component of the error weight vector became zero during internal time-stepping. (c) The linear solver initialization function (called by the user after calling CVodeCreate) failed to set the linear solver-specific lsolve field in cvode\_mem. (d) A root of one of the root functions was found both at a point t and also very near t. In any

case, the user should see the error message for details.

CV\_TOO\_CLOSE The initial time  $t_0$  and the final time  $t_{out}$  are too close to each other and the user did not specify an initial step size.

CV\_TOO\_MUCH\_WORK The solver took mxstep internal steps but still could not reach tout.

The default value for mxstep is MXSTEP\_DEFAULT = 500.

CV\_TOO\_MUCH\_ACC The solver could not satisfy the accuracy demanded by the user for some internal step.

CV\_ERR\_FAILURE Either error test failures occurred too many times (MXNEF = 7) during one internal time step, or with  $|h| = h_{min}$ .

CV\_CONV\_FAILURE Either convergence test failures occurred too many times (MXNCF = 10) during one internal time step, or with  $|h| = h_{min}$ .

CV\_LINIT\_FAIL The linear solver's initialization function failed.

CV\_LSETUP\_FAIL The linear solver's setup function failed in an unrecoverable manner.

CV\_LSOLVE\_FAIL The linear solver's solve function failed in an unrecoverable manner.

 ${\tt CV\_CONSTR\_FAIL} \quad \text{ The inequality constraints were violated and the solver was unable}$ 

to recover.

CV\_RHSFUNC\_FAIL The right-hand side function failed in an unrecoverable manner.

CV\_FIRST\_RHSFUNC\_FAIL The right-hand side function had a recoverable error at the first call.

CV\_REPTD\_RHSFUNC\_ERR Convergence test failures occurred too many times due to repeated recoverable errors in the right-hand side function. This flag will also be returned if the right-hand side function had repeated recoverable errors during the estimation of an initial step size.

CV\_UNREC\_RHSFUNC\_ERR The right-hand function had a recoverable error, but no recovery was possible. This failure mode is rare, as it can occur only if the right-hand side function fails recoverably after an error test failed while at order one.

CV\_RTFUNC\_FAIL The rootfinding function failed.

The vector yout can occupy the same space as the vector you of initial conditions that was passed to CVodeInit.

In the CV\_ONE\_STEP mode, tout is used only on the first call, and only to get the direction and a rough scale of the independent variable.

All failure return values are negative and so the test flag < 0 will trap all CVode failures.

Notes

Optional input	Function name	Default			
CVODES main solver					
Pointer to an error file	CVodeSetErrFile	stderr

Jacobian function	CVDlsSetJacFn	DQ			
CVSPILS linear solver interface					
Preconditioner functions	CVSpilsSetPreconditioner	NULL, NULL			
Jacobian-times-vector functions	CVSpilsSetJacTimes	NULL, DQ			
Ratio between linear and nonlinear tolerances	CVSpilsSetEpsLin	0.05			

Table 4.2: Optional inputs for CVODES, CVDLS, and CVSPILS

On any error return in which one or more internal steps were taken by CVode, the returned values of tret and yout correspond to the farthest point reached in the integration. On all other error returns, tret and yout are left unchanged from the previous CVode return.

# 4.5.6 Optional input functions

There are numerous optional input parameters that control the behavior of the CVODES solver. CVODES provides functions that can be used to change these optional input parameters from their default values. Table 4.2 lists all optional input functions in CVODES which are then described in detail in the remainder of this section, beginning with those for the main CVODES solver and continuing with those for the linear solver interfaces. Note that the diagonal linear solver module has no optional inputs. For the most casual use of CVODES, the reader can skip to §4.6.

We note that, on an error return, all of the optional input functions send an error message to the error handler function. We also note that all error return values are negative, so the test  ${\tt flag} < 0$  will catch all errors.

# 4.5.6.1 Main solver optional input functions

The calls listed here can be executed in any order. However, if either of the functions CVodeSetErrFile or CVodeSetErrHandlerFn is to be called, that call should be first, in order to take effect for any later error message.

### CVodeSetErrFile

Call flag = CVodeSetErrFile(cvode\_mem, errfp);

Description The function CVodeSetErrFile specifies a pointer to the file where all CVODES messages

should be directed when the default CVODES error handler function is used.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

errfp (FILE \*) pointer to output file.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value for errfp is stderr.

Passing a value of NULL disables all future error message output (except for the case in which the CVODES memory pointer is NULL). This use of CVodeSetErrFile is strongly discouraged.

If CVodeSetErrFile is to be called, it should be called before any other optional input functions, in order to take effect for any later error message.

# $\triangle$

### CVodeSetErrHandlerFn

Call flag = CVodeSetErrHandlerFn(cvode\_mem, ehfun, eh\_data);

 $\label{prop:cond} \textbf{Description} \quad \text{The function $\tt CVodeSetErrHandlerFn} \ \ \text{specifies the optional user-defined function to be}$ 

used in handling error messages.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

ehfun (CVErrHandlerFn) is the C error handler function (see §4.6.2).

eh\_data (void \*) pointer to user data passed to ehfun every time it is called.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The function enfun and data pointer eh\_data have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes Error messages indicating that the CVODES solver memory is NULL will always be directed

to stderr.

### CVodeSetUserData

Call flag = CVodeSetUserData(cvode\_mem, user\_data);

Description The function CVodeSetUserData specifies the user data block user\_data and attaches

it to the main CVODES memory block.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

user\_data (void \*) pointer to the user data.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes If specified, the pointer to user\_data is passed to all user-supplied functions that have

it as an argument. Otherwise, a NULL pointer is passed.

If user\_data is needed in user linear solver or preconditioner functions, the call to CVodeSetUserData must be made *before* the call to specify the linear solver.

### CVodeSetMaxOrd

Call flag = CVodeSetMaxOrd(cvode\_mem, maxord);

Description The function CVodeSetMaxOrd specifies the maximum order of the linear multistep

method.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

maxord (int) value of the maximum method order. This must be positive.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT The specified value maxord is  $\leq 0$ , or larger than its previous value.

Notes The default value is  $ADAMS\_Q\_MAX = 12$  for the Adams-Moulton method and  $BDF\_Q\_MAX$ 

= 5 for the BDF method. Since maxord affects the memory requirements for the internal

CVODES memory block, its value cannot be increased past its previous value.

An input value greater than the default will result in the default value.

### CVodeSetMaxNumSteps

Call flag = CVodeSetMaxNumSteps(cvode\_mem, mxsteps);

Description The function CVodeSetMaxNumSteps specifies the maximum number of steps to be taken

by the solver in its attempt to reach the next output time.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

mxsteps (long int) maximum allowed number of steps.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes Passing mxsteps = 0 results in CVODES using the default value (500).

Passing mxsteps < 0 disables the test (not recommended).

### CVodeSetMaxHnilWarns

Call flag = CVodeSetMaxHnilWarns(cvode\_mem, mxhnil);

Description The function CVodeSetMaxHnilWarns specifies the maximum number of messages issued

by the solver warning that t + h = t on the next internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

mxhnil (int) maximum number of warning messages (>0).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value is 10. A negative value for mxhnil indicates that no warning messages

should be issued.

# CVodeSetStabLimDet

Call flag = CVodeSetstabLimDet(cvode\_mem, stldet);

Description The function CVodeSetStabLimDet indicates if the BDF stability limit detection algo-

rithm should be used. See §2.3 for further details.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

 $\begin{array}{ll} \mathtt{stldet} & (\mathtt{booleantype}) \ \mathrm{flag} \ \mathrm{controlling} \ \mathrm{stability} \ \mathrm{limit} \ \mathrm{detection} \ (\mathtt{SUNTRUE} = \mathrm{on}; \\ \mathtt{SUNFALSE} = \mathrm{off}). \end{array}$ 

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT The linear multistep method is not set to CV\_BDF.

Notes

The default value is SUNFALSE. If stldet = SUNTRUE when BDF is used and the method order is greater than or equal to 3, then an internal function, CVsldet, is called to detect a possible stability limit. If such a limit is detected, then the order is reduced.

### ${\tt CVodeSetInitStep}$

Call flag = CVodeSetInitStep(cvode\_mem, hin);

Description The function CVodeSetInitStep specifies the initial step size.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hin (realtype) value of the initial step size to be attempted. Pass 0.0 to use

the default value.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes By default, CVODES estimates the initial step size to be the solution h of the equation

 $||0.5h^2\ddot{y}||_{\text{WRMS}} = 1$ , where  $\ddot{y}$  is an estimated second derivative of the solution at t0.

### CVodeSetMinStep

Call flag = CVodeSetMinStep(cvode\_mem, hmin);

Description The function CVodeSetMinStep specifies a lower bound on the magnitude of the step

size.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hmin (realtype) minimum absolute value of the step size ( $\geq 0.0$ ).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT Either hmin is nonpositive or it exceeds the maximum allowable step size.

Notes The default value is 0.0.

# CVodeSetMaxStep

Call flag = CVodeSetMaxStep(cvode\_mem, hmax);

Description The function CVodeSetMaxStep specifies an upper bound on the magnitude of the step

size.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hmax (realtype) maximum absolute value of the step size ( $\geq 0.0$ ).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT Either hmax is nonpositive or it is smaller than the minimum allowable

step size.

Notes Pass hmax = 0.0 to obtain the default value  $\infty$ .

# CVodeSetStopTime

Call flag = CVodeSetStopTime(cvode\_mem, tstop);

Description The function  ${\tt CVodeSetStopTime}$  specifies the value of the independent variable t past

which the solution is not to proceed.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

tstop (realtype) value of the independent variable past which the solution should

not proceed.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT The value of tstop is not beyond the current t value,  $t_n$ .

Notes The default, if this routine is not called, is that no stop time is imposed.

### CVodeSetMaxErrTestFails

Call flag = CVodeSetMaxErrTestFails(cvode\_mem, maxnef);

Description The function CVodeSetMaxErrTestFails specifies the maximum number of error test

failures permitted in attempting one step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

maxnef (int) maximum number of error test failures allowed on one step (>0).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value is 7.

### CVodeSetMaxNonlinIters

Call flag = CVodeSetMaxNonlinIters(cvode\_mem, maxcor);

Description The function CVodeSetMaxNonlinIters specifies the maximum number of nonlinear

solver iterations permitted per step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

maxcor (int) maximum number of nonlinear solver iterations allowed per step (>0).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

 ${\tt CV\_MEM\_NULL}$  The  ${\tt cvode\_mem}$  pointer is NULL.

Notes The default value is 3.

### CVodeSetMaxConvFails

Call flag = CVodeSetMaxConvFails(cvode\_mem, maxncf);

convergence failures permitted during one step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

maxncf (int) maximum number of allowable nonlinear solver convergence failures per step (> 0).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value is 10.

### CVodeSetNonlinConvCoef

Call flag = CVodeSetNonlinConvCoef(cvode\_mem, nlscoef);

Description The function CVodeSetNonlinConvCoef specifies the safety factor used in the nonlinear

convergence test (see  $\S 2.1$ ).

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nlscoef (realtype) coefficient in nonlinear convergence test (> 0.0).

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value is 0.1.

### CVodeSetIterType

Call flag = CVodeSetIterType(cvode\_mem, iter);

Description The function CVodeSetIterType resets the nonlinear solver iteration type to iter.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

iter (int) specifies the type of nonlinear solver iteration and may be either CV\_NEWTON or CV\_FUNCTIONAL.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT The iter value passed is neither CV\_NEWTON nor CV\_FUNCTIONAL.

Notes The nonlinear solver iteration type is initially specified in the call to CVodeCreate (see

§4.5.1). This function call is needed only if iter is being changed from its value in the prior call to CVodeCreate.

### CVodeSetConstraints

Call flag = CVodeSetConstraints(cvode\_mem, constraints);

Description The function CVodeSetConstraints specifies a vector defining inequality constraints for each component of the solution vector y.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

constraints (N\_Vector) vector of constraint flags. If constraints[i] is

0.0 then no constraint is imposed on  $y_i$ .

1.0 then  $y_i$  will be constrained to be  $y_i \ge 0.0$ .

-1.0 then  $y_i$  will be constrained to be  $y_i \leq 0.0$ .

2.0 then  $y_i$  will be constrained to be  $y_i > 0.0$ .

-2.0 then  $y_i$  will be constrained to be  $y_i < 0.0$ .

Return value The return value of flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT The constraints vector contains illegal values or the simultaneous corrector option has been selected when doing forward sensitivity analysis.

Notes

The presence of a non-NULL constraints vector that is not 0.0 in all components will cause constraint checking to be performed. However, a call with 0.0 in all components of constraints will result in an illegal input return. A NULL constraints vector will disable constraint checking.

Constraint checking when doing forward sensitivity analysis with the simultaneous corrector option is currently disallowed and will result in an illegal input return.

### 4.5.6.2 Direct linear solver interface optional input functions

The CVDLS solver interface needs a function to compute an approximation to the Jacobian matrix J(t,y). This function must be of type CVDlsJacFn. The user can supply a Jacobian function, or if using a dense or banded matrix J can use the default internal difference quotient approximation that comes with the CVDLS solver. To specify a user-supplied Jacobian function jac, CVDLS provides the function CVDlsSetJacFn. The CVDLS interface passes the pointer user\_data to the Jacobian function. This allows the user to create an arbitrary structure with relevant problem data and access it during the execution of the user-supplied Jacobian function, without using global data in the program. The pointer user\_data may be specified through CVodeSetUserData.

### CVDlsSetJacFn

Call flag = CVDlsSetJacFn(cvode\_mem, jac);

Description The function CVDlsSetJacFn specifies the Jacobian approximation function to be used.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

jac (CVDlsJacFn) user-defined Jacobian approximation function.

Return value The return value flag (of type int) is one of

 ${\tt CVDLS\_SUCCESS}$  The optional value has been successfully set.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_LMEM\_NULL The CVDLs linear solver interface has not been initialized.

Notes

By default, CVDLS uses an internal difference quotient function for dense and band matrices. If NULL is passed to jac, this default function is used. An error will occur if no jac is supplied when using a sparse matrix.

The function type CVDlsJacFn is described in §4.6.5.

### 4.5.6.3 Iterative linear solver interface optional input functions

If preconditioning is utilized with the CVSPILS linear solver interface, then the user must supply a preconditioner solve function psolve and specify its name in a call to CVSpilsSetPreconditioner. The evaluation and preprocessing of any Jacobian-related data needed by the user's preconditioner solve function is done in the optional user-supplied function psetup. Both of these functions are fully specified in §4.6. If used, the psetup function should also be specified in the call to CVSpilsSetPreconditioner.

The pointer user\_data received through CVodeSetUserData (or a pointer to NULL if user\_data was not specified) is passed to the preconditioner psetup and psolve functions. This allows the user to create an arbitrary structure with relevant problem data and access it during the execution of the user-supplied preconditioner functions without using global data in the program.

The CVSPILS solver interface requires a function to compute an approximation to the product between the Jacobian matrix J(t,y) and a vector v. The user can supply a Jacobian-times-vector approximation function or use the default internal difference quotient function that comes with the CVSPILS interface. A user-defined Jacobian-vector function must be of type CVSpilsJacTimesVecFn and can be specified through a call to CVSpilsSetJacTimes (see §4.6.6 for specification details). As with the user-supplied preconditioner functions, the evaluation and processing of any Jacobian-related data needed by the user's Jacobian-times-vector function is done in the optional user-supplied

function jtsetup (see §4.6.7 for specification details). As with the preconditioner functions, a pointer to the user-defined data structure, user\_data, specified through CVodeSetUserData (or a NULL pointer otherwise) is passed to the Jacobian-times-vector setup and product functions, jtsetup and jtimes, each time they are called.

Finally, as described in Section 2.1, the CVSPILS interface requires that iterative linear solvers stop when the norm of the preconditioned residual is less than  $0.05 \cdot (0.1\epsilon)$ , where  $\epsilon$  is the nonlinear solver tolerance. The user may adjust this linear solver tolerance by calling the function CVSpilsSetEpsLin.

### CVSpilsSetPreconditioner

Call flag = CVSpilsSetPreconditioner(cvode\_mem, psetup, psolve);

 $\label{preconditioner} Description \quad The \ function \ {\tt CVSpilsSetPreconditioner} \ specifies \ the \ preconditioner \ setup \ and \ solve$ 

functions.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

psetup (CVSpilsPrecSetupFn) user-defined preconditioner setup function. Pass

NULL if no setup is necessary.

psolve (CVSpilsPrecSolveFn) user-defined preconditioner solve function.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional values have been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_SUNLS\_FAIL An error occurred when setting up preconditioning in the SUN-LINSOL object used by the CVSPILS interface.

Notes The function type CVSpilsPrecSolveFn is de

The function type CVSpilsPrecSolveFn is described in §4.6.8. The function type CVSpilsPrecSetupFn is described in §4.6.9.

### CVSpilsSetJacTimes

Call flag = CVSpilsSetJacTimes(cvode\_mem, jtsetup, jtimes);

 $\label{lem:decomposition} \textbf{Description} \quad \textbf{The function CVSpilsSetJacTimes} \ \ \text{specifies the Jacobian-vector setup and product}$ 

functions.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

jtsetup (CVSpilsJacTimesSetupFn) user-defined Jacobian-vector setup function. Pass

NULL if no setup is necessary.

jtimes (CVSpilsJacTimesVecFn) user-defined Jacobian-vector product function.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_SUNLS\_FAIL An error occurred when setting up the system matrix-times-vector routines in the SUNLINSOL object used by the CVSPILS interface.

Notes By default, the CVSPILS linear solvers use an internal difference quotient function. If NULL is passed to jtimes, this default function is used.

The function type CVSpilsJacTimesSetupFn is described in §4.6.7.

The function type CVSpilsJacTimesVecFn is described in §4.6.6.

### CVSpilsSetEpsLin

Call flag = CVSpilsSetEpsLin(cvode\_mem, eplifac);

Description The function CVSpilsSetEpsLin specifies the factor by which the Krylov linear solver's

convergence test constant is reduced from the Newton iteration test constant.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

eplifac (realtype) linear convergence safety factor ( $\geq 0.0$ ).

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_ILL\_INPUT The factor eplifac is negative.

Notes The default value is 0.05.

If eplifac = 0.0 is passed, the default value is used.

### 4.5.6.4 Rootfinding optional input functions

The following functions can be called to set optional inputs to control the rootfinding algorithm.

### CVodeSetRootDirection

Call flag = CVodeSetRootDirection(cvode\_mem, rootdir);

Description The function CVodeSetRootDirection specifies the direction of zero-crossings to be

located and returned.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

rootdir (int \*) state array of length nrtfn, the number of root functions  $q_i$ , as spec-

ified in the call to the function CVodeRootInit. A value of 0 for rootdir[i] indicates that crossing in either direction for  $g_i$  should be reported. A value of +1 or -1 indicates that the solver should report only zero-crossings where

 $g_i$  is increasing or decreasing, respectively.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT rootfinding has not been activated through a call to CVodeRootInit.

Notes The default behavior is to monitor for both zero-crossing directions.

### CVodeSetNoInactiveRootWarn

Call flag = CVodeSetNoInactiveRootWarn(cvode\_mem);

Description The function CVodeSetNoInactiveRootWarn disables issuing a warning if some root

function appears to be identically zero at the beginning of the integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes CVODES will not report the initial conditions as a possible zero-crossing (assuming that

one or more components  $g_i$  are zero at the initial time). However, if it appears that some  $g_i$  is identically zero at the initial time (i.e.,  $g_i$  is zero at the initial time and after the first step), CVODES will issue a warning which can be disabled with this optional

input function.

# 4.5.7 Interpolated output function

An optional function CVodeGetDky is available to obtain additional output values. This function should only be called after a successful return from CVode as it provides interpolated values either of y or of its derivatives (up to the current order of the integration method) interpolated to any value of t in the last internal step taken by CVODES.

The call to the CVodeGetDky function has the following form:

```
CVodeGetDky
```

Notes

Call flag = CVodeGetDky(cvode\_mem, t, k, dky);

Description The function CVodeGetDky computes the k-th derivative of the function y at time t, i.e.

 $d^{(k)}y/dt^{(k)}(t)$ , where  $t_n-h_u \leq t \leq t_n$ ,  $t_n$  denotes the current internal time reached, and  $h_u$  is the last internal step size successfully used by the solver. The user may request k

 $=0,1,\ldots,q_u$ , where  $q_u$  is the current order (optional output qlast).

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

t (realtype) the value of the independent variable at which the derivative is

to be evaluated.

k (int) the derivative order requested.

dky (N\_Vector) vector containing the derivative. This vector must be allocated

by the user.

Return value The return value flag (of type int) is one of

CV\_SUCCESS CVodeGetDky succeeded.

CV\_BAD\_K k is not in the range  $0, 1, \ldots, q_u$ .

CV\_BAD\_T t is not in the interval  $[t_n - h_u, t_n]$ .

CV\_BAD\_DKY The dky argument was NULL.

CV\_MEM\_NULL The cvode\_mem argument was NULL.

It is only legal to call the function CVodeGetDky after a successful return from CVode. See CVodeGetCurrentTime, CVodeGetLastOrder, and CVodeGetLastStep in the next

section for access to  $t_n$ ,  $q_u$ , and  $h_u$ , respectively.

# 4.5.8 Optional output functions

CVODES provides an extensive set of functions that can be used to obtain solver performance information. Table 4.3 lists all optional output functions in CVODES, which are then described in detail in the remainder of this section.

Some of the optional outputs, especially the various counters, can be very useful in determining how successful the CVODES solver is in doing its job. For example, the counters nsteps and nfevals provide a rough measure of the overall cost of a given run, and can be compared among runs with differing input options to suggest which set of options is most efficient. The ratio nniters/nsteps measures the performance of the Newton iteration in solving the nonlinear systems at each time step; typical values for this range from 1.1 to 1.8. The ratio njevals/nniters (in the case of a direct linear solver), and the ratio npevals/nniters (in the case of an iterative linear solver) measure the overall degree of nonlinearity in these systems, and also the quality of the approximate Jacobian or preconditioner being used. Thus, for example, njevals/nniters can indicate if a user-supplied Jacobian is inaccurate, if this ratio is larger than for the case of the corresponding internal Jacobian. The ratio nliters/nniters measures the performance of the Krylov iterative linear solver, and thus (indirectly) the quality of the preconditioner.

### 4.5.8.1 SUNDIALS version information

The following functions provide a way to get SUNDIALS version information at runtime.

Table 4.3: Optional outputs from CVODES, CVDLS, CVDIAG, and CVSPILS

Optional output	Function name				
CVODES main sol					
Size of CVODES real and integer workspaces	CVodeGetWorkSpace				
Cumulative number of internal steps	CVodeGetNumSteps				
No. of calls to r.h.s. function	CVodeGetNumRhsEvals				
No. of calls to linear solver setup function	CVodeGetNumLinSolvSetups				
No. of local error test failures that have occurred	CVodeGetNumErrTestFails				
Order used during the last step	CVodeGetLastOrder				
Order to be attempted on the next step	CVodeGetCurrentOrder				
No. of order reductions due to stability limit detection	CVodeGetNumStabLimOrderReds				
Actual initial step size used	CVodeGetActualInitStep				
Step size used for the last step	CVodeGetLastStep				
Step size to be attempted on the next step	CVodeGetCurrentStep				
Current internal time reached by the solver	CVodeGetCurrentTime				
Suggested factor for tolerance scaling	CVodeGetTolScaleFactor				
Error weight vector for state variables	CVodeGetErrWeights				
Estimated local error vector	CVodeGetEstLocalErrors				
No. of nonlinear solver iterations	CVodeGetNumNonlinSolvIters				
No. of nonlinear convergence failures	CVodeGetNumNonlinSolvConvFails				
All CVODES integrator statistics	CVodeGetIntegratorStats				
CVODES nonlinear solver statistics	CVodeGetNonlinSolvStats				
Array showing roots found	CvodeGetRootInfo				
No. of calls to user root function	CVodeGetNumGEvals				
Name of constant associated with a return flag	CVodeGetReturnFlagName				
CVDLS linear solver in	nterface				
Size of real and integer workspaces	CVDlsGetWorkSpace				
No. of Jacobian evaluations	CVDlsGetNumJacEvals				
No. of r.h.s. calls for finite diff. Jacobian evals.	CVDlsGetNumRhsEvals				
Last return from a linear solver function	CVDlsGetLastFlag				
Name of constant associated with a return flag	CVDlsGetReturnFlagName				
CVDIAG linear solver i	nterface				
Size of CVDIAG real and integer workspaces	CVDiagGetWorkSpace				
No. of r.h.s. calls for finite diff. Jacobian evals.	CVDiagGetNumRhsEvals				
Last return from a CVDIAG function	${\tt CVDiagGetLastFlag}$				
Name of constant associated with a return flag	CVDiagGetReturnFlagName				
CVSPILS linear solver interface					
Size of real and integer workspaces	CVSpilsGetWorkSpace				
No. of linear iterations	CVSpilsGetNumLinIters				
No. of linear convergence failures	CVSpilsGetNumConvFails				
No. of preconditioner evaluations	CVSpilsGetNumPrecEvals				
No. of preconditioner solves	CVSpilsGetNumPrecSolves				
No. of Jacobian-vector setup evaluations	CVSpilsGetNumJTSetupEvals				
No. of Jacobian-vector product evaluations	CVSpilsGetNumJtimesEvals				
No. of r.h.s. calls for finite diff. Jacobian-vector evals.	CVSpilsGetNumRhsEvals				
Last return from a linear solver function	CVSpilsGetLastFlag				
Name of constant associated with a return flag	CVSpilsGetReturnFlagName				

### SUNDIALSGetVersion

Call flag = SUNDIALSGetVersion(version, len);

Description The function SUNDIALSGetVersion fills a character array with SUNDIALS version infor-

mation.

Arguments version (char \*) character array to hold the SUNDIALS version information.

len (int) allocated length of the version character array.

Return value If successful, SUNDIALSGetVersion returns 0 and version contains the SUNDIALS ver-

sion information. Otherwise, it returns -1 and version is not set (the input character

array is too short).

Notes A string of 25 characters should be sufficient to hold the version information. Any

trailing characters in the version array are removed.

### SUNDIALSGetVersionNumber

Call flag = SUNDIALSGetVersionNumber(&major, &minor, &patch, label, len);

Description The function SUNDIALSGetVersionNumber set integers for the SUNDIALS major, minor,

and patch release numbers and fills a character array with the release label if applicable.

Arguments major (int) SUNDIALS release major version number.

minor (int) SUNDIALS release minor version number.

patch (int) SUNDIALS release patch version number.

label (char \*) character array to hold the SUNDIALS release label.

len (int) allocated length of the label character array.

Return value If successful, SUNDIALSGetVersionNumber returns 0 and the major, minor, patch, and

label values are set. Otherwise, it returns -1 and the values are not set (the input character array is too short)

character array is too short).

Notes A string of 10 characters should be sufficient to hold the label information. If a label is not used in the release version, no information is copied to label. Any trailing

characters in the label array are removed.

### 4.5.8.2 Main solver optional output functions

CVODES provides several user-callable functions that can be used to obtain different quantities that may be of interest to the user, such as solver workspace requirements, solver performance statistics, as well as additional data from the CVODES memory block (a suggested tolerance scaling factor, the error weight vector, and the vector of estimated local errors). Functions are also provided to extract statistics related to the performance of the CVODES nonlinear solver used. As a convenience, additional information extraction functions provide the optional outputs in groups. These optional output functions are described next.

# ${\tt CVodeGetWorkSpace}$

Call flag = CVodeGetWorkSpace(cvode\_mem, &lenrw, &leniw);

Description The function CVodeGetWorkSpace returns the CVODES real and integer workspace sizes.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lenrw (long int) the number of realtype values in the CVODES workspace.

leniw (long int) the number of integer values in the CVODES workspace.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output values have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes

In terms of the problem size N, the maximum method order maxord, and the number nrtfn of root functions (see §4.5.4), the actual size of the real workspace, in realtype words, is given by the following:

- base value: lenrw =  $96 + (maxord+5) * N_r + 3*nrtfn;$
- using CVodeSVtolerances: lenrw = lenrw  $+N_r$ ;
- with constraint checking (see CVodeSetConstraints); lenrw = lenrw  $+N_r$ ;

where  $N_r$  is the number of real words in one N\_Vector ( $\approx N$ ).

The size of the integer workspace (without distinction between int and long int words) is given by:

- base value: leniw =  $40 + (maxord+5) * N_i + nrtfn;$
- using CVodeSVtolerances: leniw = leniw  $+N_i$ ;
- with constraint checking: lenrw = lenrw + $N_i$ ;

where  $N_i$  is the number of integer words in one N\_Vector (= 1 for NVECTOR\_SERIAL and 2\*npes for NVECTOR\_PARALLEL and npes processors).

For the default value of maxord, no rootfinding, no constraints, and without using CVodeSVtolerances, these lengths are given roughly by:

- For the Adams method: lenrw = 96 + 17N and leniw = 57
- For the BDF method: lenrw = 96 + 10N and leniw = 50

Note that additional memory is allocated if quadratures and/or forward sensitivity integration is enabled. See §4.7.1 and §5.2.1 for more details.

### CVodeGetNumSteps

Call flag = CVodeGetNumSteps(cvode\_mem, &nsteps);

The function CVodeGetNumSteps returns the cumulative number of internal steps taken Description by the solver (total so far).

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

> (long int) number of steps taken by CVODES. nsteps

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

### CVodeGetNumRhsEvals

Call flag = CVodeGetNumRhsEvals(cvode\_mem, &nfevals);

Description The function CVodeGetNumRhsEvals returns the number of calls to the user's right-hand side function.

cvode\_mem (void \*) pointer to the CVODES memory block. Arguments

> (long int) number of calls to the user's f function. nfevals

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

The nfevals value returned by CVodeGetNumRhsEvals does not account for calls made to f by a linear solver or preconditioner module.

Notes

### CVodeGetNumLinSolvSetups

Call flag = CVodeGetNumLinSolvSetups(cvode\_mem, &nlinsetups);

Description The function CVodeGetNumLinSolvSetups returns the number of calls made to the

linear solver's setup function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nlinsetups (long int) number of calls made to the linear solver setup function.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

### CVodeGetNumErrTestFails

Call flag = CVodeGetNumErrTestFails(cvode\_mem, &netfails);

Description The function CVodeGetNumErrTestFails returns the number of local error test failures

that have occurred.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

netfails (long int) number of error test failures.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

### CVodeGetLastOrder

Call flag = CVodeGetLastOrder(cvode\_mem, &qlast);

Description The function CVodeGetLastOrder returns the integration method order used during the

last internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

qlast (int) method order used on the last internal step.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

# CVodeGetCurrentOrder

Call flag = CVodeGetCurrentOrder(cvode\_mem, &qcur);

Description The function CVodeGetCurrentOrder returns the integration method order to be used

on the next internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

qcur (int) method order to be used on the next internal step.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

### CVodeGetLastStep

Call flag = CVodeGetLastStep(cvode\_mem, &hlast);

Description The function CVodeGetLastStep returns the integration step size taken on the last

internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hlast (realtype) step size taken on the last internal step.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

# CVodeGetCurrentStep

Call flag = CVodeGetCurrentStep(cvode\_mem, &hcur);

Description The function CVodeGetCurrentStep returns the integration step size to be attempted

on the next internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hcur (realtype) step size to be attempted on the next internal step.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

### ${\tt CVodeGetActualInitStep}$

Call flag = CVodeGetActualInitStep(cvode\_mem, &hinused);

Description The function CVodeGetActualInitStep returns the value of the integration step size

used on the first step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

hinused (realtype) actual value of initial step size.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes Even if the value of the initial integration step size was specified by the user through

a call to CVodeSetInitStep, this value might have been changed by CVODES to ensure that the step size is within the prescribed bounds  $(h_{\min} \leq h_0 \leq h_{\max})$ , or to satisfy the

local error test condition.

### CVodeGetCurrentTime

Call flag = CVodeGetCurrentTime(cvode\_mem, &tcur);

Description The function CVodeGetCurrentTime returns the current internal time reached by the

solver.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

tcur (realtype) current internal time reached.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### CVodeGetNumStabLimOrderReds

Call flag = CVodeGetNumStabLimOrderReds(cvode\_mem, &nslred);

 $Description \quad The \ function \ {\tt CVodeGetNumStabLimOrderReds} \ \ returns \ the \ number \ of \ order \ reductions$ 

dictated by the BDF stability limit detection algorithm (see §2.3).

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nslred (long int) number of order reductions due to stability limit detection.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes If the stability limit detection algorithm was not initialized (CVodeSetStabLimDet was

not called), then nslred = 0.

#### CVodeGetTolScaleFactor

Call flag = CVodeGetTolScaleFactor(cvode\_mem, &tolsfac);

Description The function CVodeGetTolScaleFactor returns a suggested factor by which the user's

tolerances should be scaled when too much accuracy has been requested for some internal step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

tolsfac (realtype) suggested scaling factor for user-supplied tolerances.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### CVodeGetErrWeights

Call flag = CVodeGetErrWeights(cvode\_mem, eweight);

Description The function CVodeGetErrWeights returns the solution error weights at the current

time. These are the reciprocals of the  $W_i$  given by (2.7).

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

eweight (N\_Vector) solution error weights at the current time.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The user must allocate memory for eweight.

#### CVodeGetEstLocalErrors

Call flag = CVodeGetEstLocalErrors(cvode\_mem, ele);

Description The function CVodeGetEstLocalErrors returns the vector of estimated local errors.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

ele (N\_Vector) estimated local errors.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

 $\triangle$ 

Notes The user must allocate memory for ele.

The values returned in ele are valid only if CVode returned a non-negative value.

The ele vector, together with the eweight vector from CVodeGetErrWeights, can be used to determine how the various components of the system contributed to the estimated local error test. Specifically, that error test uses the RMS norm of a vector whose components are the products of the components of these two vectors. Thus, for example, if there were recent error test failures, the components causing the failures are those with largest values for the products, denoted loosely as eweight[i]\*ele[i].

#### ${\tt CVodeGetIntegratorStats}$

Call flag = CVodeGetIntegratorStats(cvode\_mem, &nsteps, &nfevals, &nlinsetups, &netfails, &qlast, &qcur, &hinused, &hlast, &hcur, &tcur);

Description The function CVodeGetIntegratorStats returns the CVODES integrator statistics as a group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nsteps (long int) number of steps taken by CVODES.

nfevals (long int) number of calls to the user's f function.

nlinsetups (long int) number of calls made to the linear solver setup function.

netfails (long int) number of error test failures.

qlast (int) method order used on the last internal step.

qcur (int) method order to be used on the next internal step.

hinused (realtype) actual value of initial step size.

hlast (realtype) step size taken on the last internal step.

hcur (realtype) step size to be attempted on the next internal step.

tcur (realtype) current internal time reached.

Return value The return value flag (of type int) is one of

CV\_SUCCESS the optional output values have been successfully set.

CV\_MEM\_NULL the cvode\_mem pointer is NULL.

#### CVodeGetNumNonlinSolvIters

Call flag = CVodeGetNumNonlinSolvIters(cvode\_mem, &nniters);

 $Description \quad The \ function \ {\tt CVodeGetNumNonlinSolvIters} \ \ {\tt returns} \ \ the \ number \ of \ nonlinear \ (function \ {\tt cvodeGetNumNonlinSolvIters})$ 

tional or Newton) iterations performed.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nniters (long int) number of nonlinear iterations performed.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output values have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### CVodeGetNumNonlinSolvConvFails

Call flag = CVodeGetNumNonlinSolvConvFails(cvode\_mem, &nncfails);

Description The function CVodeGetNumNonlinSolvConvFails returns the number of nonlinear con-

vergence failures that have occurred.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### CVodeGetNonlinSolvStats

Call flag = CVodeGetNonlinSolvStats(cvode\_mem, &nniters, &nncfails);

Description The function CVodeGetNonlinSolvStats returns the CVODES nonlinear solver statistics

as a group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nniters (long int) number of nonlinear iterations performed. nncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### CVodeGetReturnFlagName

Description The function CVodeGetReturnFlagName returns the name of the CVODES constant cor-

responding to flag.

Arguments The only argument, of type int, is a return flag from a CVODES function.

Return value The return value is a string containing the name of the corresponding constant.

#### 4.5.8.3 Rootfinding optional output functions

There are two optional output functions associated with rootfinding.

#### CVodeGetRootInfo

Call flag = CVodeGetRootInfo(cvode\_mem, rootsfound);

Description The function CVodeGetRootInfo returns an array showing which functions were found

to have a root.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

rootsfound (int \*) array of length nrtfn with the indices of the user functions  $g_i$  found to have a root. For  $i = 0, \ldots, \text{nrtfn}-1$ , rootsfound[i]  $\neq 0$  if  $g_i$  has a root, and = 0 if not.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output values have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes Note that, for the components  $q_i$  for which a root was found, the sign of rootsfound [i]

indicates the direction of zero-crossing. A value of +1 indicates that  $g_i$  is increasing,

while a value of -1 indicates a decreasing  $g_i$ .

The user must allocate memory for the vector rootsfound.

#### CVodeGetNumGEvals

Call flag = CVodeGetNumGEvals(cvode\_mem, &ngevals);

Description The function CVodeGetNumGEvals returns the cumulative number of calls made to the

user-supplied root function g.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

ngevals (long int) number of calls made to the user's function g thus far.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

#### 4.5.8.4 Direct linear solver interface optional output functions

The following optional outputs are available from the CVDLS modules: workspace requirements, number of calls to the Jacobian routine, number of calls to the right-hand side routine for finite-difference Jacobian approximation, and last return value from a CVDLS function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added (e.g. lenrwLS).

#### CVDlsGetWorkSpace

Call flag = CVDlsGetWorkSpace(cvode\_mem, &lenrwLS, &leniwLS);

Description The function CVDlsGetWorkSpace returns the sizes of the real and integer workspaces

used by the CVDLS linear solver interface.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lenrwLS (long int) the number of realtype values in the CVDLS workspace.

leniwLS (long int) the number of integer values in the CVDLS workspace.

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The optional output values have been successfully set.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_LMEM\_NULL The CVDLS linear solver has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory allocated within this interface and to memory allocated by the SUNLINSOL object attached to it. The template Jacobian matrix allocated by the user outside of CVDLS is not

included in this report.

#### CVDlsGetNumJacEvals

Call flag = CVDlsGetNumJacEvals(cvode\_mem, &njevals);

Description The function CVDlsGetNumJacEvals returns the number of calls made to the CVDLS

Jacobian approximation function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

njevals (long int) the number of calls to the Jacobian function.

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The optional output value has been successfully set.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_LMEM\_NULL The CVDLS linear solver has not been initialized.

#### CVDlsGetNumRhsEvals

Call flag = CVDlsGetNumRhsEvals(cvode\_mem, &nfevalsLS);

Description The function CVDlsGetNumRhsEvals returns the number of calls made to the user-

supplied right-hand side function due to the finite difference Jacobian approximation.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfevalsLS (long int) the number of calls made to the user-supplied right-hand side

function.

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The optional output value has been successfully set.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_LMEM\_NULL The CVDLS linear solver has not been initialized.

Notes The value nfevalsLS is incremented only if one of the default internal difference quotient

functions (dense or banded) is used.

#### CVDlsGetLastFlag

Call flag = CVDlsGetLastFlag(cvode\_mem, &lsflag);

Description The function CVDlsGetLastFlag returns the last return value from a CVDLs routine.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lsflag (long int) the value of the last return flag from a CVDLS function.

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The optional output value has been successfully set.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_LMEM\_NULL The CVDLs linear solver has not been initialized.

Notes If the SUNLINSOL\_DENSE or SUNLINSOL\_BAND setup function failed (CVode returned

CV\_LSETUP\_FAIL), then the value of lsflag is equal to the column index (numbered from one) at which a zero diagonal element was encountered during the LU factorization

of the (dense or banded) Jacobian matrix.

#### CVDlsGetReturnFlagName

Call name = CVDlsGetReturnFlagName(lsflag);

Description The function CVDlsGetReturnFlagName returns the name of the CVDLS constant corre-

sponding to 1sflag.

Arguments The only argument, of type long int, is a return flag from a CVDLS function.

Return value The return value is a string containing the name of the corresponding constant.

If  $1 \leq lsflag \leq N$  (LU factorization failed), this routine returns "NONE".

#### 4.5.8.5 Iterative linear solver interface optional output functions

The following optional outputs are available from the CVSPILS modules: workspace requirements, number of linear iterations, number of linear convergence failures, number of calls to the preconditioner setup and solve routines, number of calls to the Jacobian-vector setup and product routines, number of calls to the right-hand side routine for finite-difference Jacobian-vector product approximation, and last return value from a linear solver function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added (e.g. lenrwLS).

#### CVSpilsGetWorkSpace

Call flag = CVSpilsGetWorkSpace(cvode\_mem, &lenrwLS, &leniwLS);

 $\label{thm:cvspilsGetWorkSpace} Description \quad The \ function \ {\tt CVSpilsGetWorkSpace} \ returns \ the \ global \ sizes \ of \ the \ {\tt CVSPILS} \ real \ and \ and \ {\tt CVSPILS} \ real \ re$ 

integer workspaces.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lenrwLS (long int) the number of realtype values in the CVSPILS workspace.

leniwLS (long int) the number of integer values in the CVSPILS workspace.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory allo-

cated within this interface and to memory allocated by the SUNLINSOL object attached

to it.

In a parallel setting, the above values are global (i.e., summed over all processors).

#### CVSpilsGetNumLinIters

Call flag = CVSpilsGetNumLinIters(cvode\_mem, &nliters);

Description The function CVSpilsGetNumLinIters returns the cumulative number of linear itera-

tions.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nliters (long int) the current number of linear iterations.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### ${\tt CVSpilsGetNumConvFails}$

Call flag = CVSpilsGetNumConvFails(cvode\_mem, &nlcfails);

Description The function CVSpilsGetNumConvFails returns the cumulative number of linear con-

vergence failures.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nlcfails (long int) the current number of linear convergence failures.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### ${\tt CVSpilsGetNumPrecEvals}$

Call flag = CVSpilsGetNumPrecEvals(cvode\_mem, &npevals);

Description The function CVSpilsGetNumPrecEvals returns the number of preconditioner evalua-

tions, i.e., the number of calls made to psetup with jok = SUNFALSE.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

npevals (long int) the current number of calls to psetup.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### CVSpilsGetNumPrecSolves

Call flag = CVSpilsGetNumPrecSolves(cvode\_mem, &npsolves);

Description The function CVSpilsGetNumPrecSolves returns the cumulative number of calls made

to the preconditioner solve function, psolve.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

npsolves (long int) the current number of calls to psolve.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### ${\tt CVSpilsGetNumJTSetupEvals}$

Call flag = CVSpilsGetNumJTSetupEvals(cvode\_mem, &njtsetup);

Description The function CVSpilsGetNumJTSetupEvals returns the cumulative number of calls

made to the Jacobian-vector setup function jtsetup.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

njtsetup (long int) the current number of calls to jtsetup.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### ${\tt CVSpilsGetNumJtimesEvals}$

Call flag = CVSpilsGetNumJtimesEvals(cvode\_mem, &njvevals);

Description The function CVSpilsGetNumJtimesEvals returns the cumulative number of calls made

to the Jacobian-vector function jtimes.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

njvevals (long int) the current number of calls to jtimes.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

#### CVSpilsGetNumRhsEvals

Call flag = CVSpilsGetNumRhsEvals(cvode\_mem, &nfevalsLS);

Description The function CVSpilsGetNumRhsEvals returns the number of calls to the user right-

hand side function for finite difference Jacobian-vector product approximation.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfevalsLS (long int) the number of calls to the user right-hand side function.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

Notes The value nfevalsLS is incremented only if the default CVSpilsDQJtimes difference

quotient function is used.

#### CVSpilsGetLastFlag

Call flag = CVSpilsGetLastFlag(cvode\_mem, &lsflag);

Description The function CVSpilsGetLastFlag returns the last return value from a CVSPILS routine.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lsflag (long int) the value of the last return flag from a CVSPILS function.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

Notes

If the CVSPILS setup function failed (CVode returned CV\_LSETUP\_FAIL), 1sflag will be SUNLS\_PSET\_FAIL\_UNREC, SUNLS\_ASET\_FAIL\_UNREC, or SUNLS\_PACKAGE\_FAIL\_UNREC.

If the CVSPILS solve function failed (CVode returned CV\_LSOLVE\_FAIL), lsflag contains the error return flag from the SUNLINSOL object, which will be one of: SUNLS\_MEM\_NULL, indicating that the SUNLINSOL memory is NULL; SUNLS\_ATIMES\_FAIL\_UNREC, indicating an unrecoverable failure in the J\*v function; SUNLS\_PSOLVE\_FAIL\_UNREC, indicating that the preconditioner solve function psolve failed unrecoverably; SUNLS\_GS\_FAIL, indicating a failure in the Gram-Schmidt procedure (SPGMR and SPFGMR only); SUNLS\_QRSOL\_FAIL, indicating that the matrix R was found to be singular during the QR solve phase (SPGMR and SPFGMR only); or SUNLS\_PACKAGE\_FAIL\_UNREC, indicating an unrecoverable failure in an external iterative linear solver package.

#### CVSpilsGetReturnFlagName

Call name = CVSpilsGetReturnFlagName(lsflag);

Description The function CVSpilsGetReturnFlagName returns the name of the CVSPILS constant

corresponding to lsflag.

Arguments The only argument, of type long int, is a return flag from a CVSPILS function.

Return value The return value is a string containing the name of the corresponding constant.

#### Diagonal linear solver interface optional output functions 4.5.8.6

The following optional outputs are available from the CVDIAG module: workspace requirements, number of calls to the right-hand side routine for finite-difference Jacobian approximation, and last return value from a CVDIAG function. Note that, where the name of an output would otherwise conflict with the name of an optional output from the main solver, a suffix LS (for Linear Solver) has been added here (e.g. lenrwLS).

#### CVDiagGetWorkSpace

Call flag = CVDiagGetWorkSpace(cvode\_mem, &lenrwLS, &leniwLS);

Description The function CVDiagGetWorkSpace returns the CVDIAG real and integer workspace sizes.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block. LenrwLS (long int) the number of realtype values in the CVDIAG workspace.

leniwLS (long int) the number of integer values in the CVDIAG workspace.

Return value The return value flag (of type int) is one of

CVDIAG\_SUCCESS The optional output value have been successfully set.

CVDIAG\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDIAG\_LMEM\_NULL The CVDIAG linear solver has not been initialized.

Notes In terms of the problem size N, the actual size of the real workspace is roughly 3N

realtype words.

#### CVDiagGetNumRhsEvals

Call flag = CVDiagGetNumRhsEvals(cvode\_mem, &nfevalsLS);

Description The function CVDiagGetNumRhsEvals returns the number of calls made to the user-

supplied right-hand side function due to the finite difference Jacobian approximation.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfevalsLS (long int) the number of calls made to the user-supplied right-hand side

function.

Return value The return value flag (of type int) is one of

CVDIAG\_SUCCESS The optional output value has been successfully set.

CVDIAG\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDIAG\_LMEM\_NULL The CVDIAG linear solver has not been initialized.

Notes The number of diagonal approximate Jacobians formed is equal to the number of calls

made to the linear solver setup function (see CVodeGetNumLinSolvSetups).

#### CVDiagGetLastFlag

Call flag = CVDiagGetLastFlag(cvode\_mem, &lsflag);

Description The function CVDiagGetLastFlag returns the last return value from a CVDIAG routine.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

1sflag (long int) the value of the last return flag from a CVDIAG function.

Return value The return value flag (of type int) is one of

CVDIAG\_SUCCESS The optional output value has been successfully set.

CVDIAG\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDIAG\_LMEM\_NULL The CVDIAG linear solver has not been initialized.

Notes If the CVDIAG setup function failed (CVode returned CV\_LSETUP\_FAIL), the value of

lsflag is equal to CVDIAG\_INV\_FAIL, indicating that a diagonal element with value zero was encountered. The same value is also returned if the CVDIAG solve function failed

(CVode returned CV\_LSOLVE\_FAIL).

#### CVDiagGetReturnFlagName

Call name = CVDiagGetReturnFlagName(lsflag);

Description The function CVDiagGetReturnFlagName returns the name of the CVDIAG constant

corresponding to lsflag.

Arguments The only argument, of type long int, is a return flag from a CVDIAG function.

Return value The return value is a string containing the name of the corresponding constant.

#### 4.5.9 CVODES reinitialization function

The function CVodeReInit reinitializes the main CVODES solver for the solution of a new problem, where a prior call to CVodeInit been made. The new problem must have the same size as the previous one. CVodeReInit performs the same input checking and initializations that CVodeInit does, but does no memory allocation, as it assumes that the existing internal memory is sufficient for the new problem. A call to CVodeReInit deletes the solution history that was stored internally during the previous integration. Following a successful call to CVodeReInit, call CVode again for the solution of the new problem.

The use of CVodeReInit requires that the maximum method order, denoted by maxord, be no larger for the new problem than for the previous problem. This condition is automatically fulfilled if the multistep method parameter lmm is unchanged (or changed from CV\_ADAMS to CV\_BDF) and the default value for maxord is specified.

If there are changes to the linear solver specifications, make the appropriate calls to either the linear solver objects themselves, or to the CVDLS or CVSPILS interface routines, as described in §4.5.3. Otherwise, all solver inputs set previously remain in effect.

One important use of the CVodeReInit function is in the treating of jump discontinuities in the RHS function. Except in cases of fairly small jumps, it is usually more efficient to stop at each point of discontinuity and restart the integrator with a readjusted ODE model, using a call to CVodeReInit. To stop when the location of the discontinuity is known, simply make that location a value of tout. To stop when the location of the discontinuity is determined by the solution, use the rootfinding feature. In either case, it is critical that the RHS function not incorporate the discontinuity, but rather have a smooth extention over the discontinuity, so that the step across it (and subsequent rootfinding, if used) can be done efficiently. Then use a switch within the RHS function (communicated through user\_data) that can be flipped between the stopping of the integration and the restart, so that the restarted problem uses the new values (which have jumped). Similar comments apply if there is to be a jump in the dependent variable vector.

#### CVodeReInit

Call flag = CVodeReInit(cvode\_mem, t0, y0);

Description The function CVodeReInit provides required problem specifications and reinitializes

CVODES.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

t0 (realtype) is the initial value of t. y0 (N\_Vector) is the initial value of y.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeReInit was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_NO\_MALLOC Memory space for the CVODES memory block was not allocated through a previous call to CVodeInit.

CV\_ILL\_INPUT An input argument to CVodeReInit has an illegal value.

Notes If an error occurred, CVodeReInit also sends an error message to the error handler function.

# 4.6 User-supplied functions

The user-supplied functions consist of one function defining the ODE, (optionally) a function that handles error and warning messages, (optionally) a function that provides the error weight vector, (optionally) one or two functions that provide Jacobian-related information for the linear solver (if Newton iteration is chosen), and (optionally) one or two functions that define the preconditioner for use in any of the Krylov iterative algorithms.

## 4.6.1 ODE right-hand side

The user must provide a function of type CVRhsFn defined as follows:

CVRhsFn

Definition typedef int (\*CVRhsFn)(realtype t, N\_Vector y, N\_Vector ydot, void \*user\_data);

Purpose This function computes the ODE right-hand side for a given value of the independent variable t and state vector y.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t).

ydot is the output vector f(t, y).

user\_data is the user\_data pointer passed to CVodeSetUserData.

Return value A CVRhsFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecov-

erably (in which case the integration is halted and CV\_RHSFUNC\_FAIL is returned).

Notes Allocation of memory for ydot is handled within CVODES.

A recoverable failure error return from the CVRhsFn is typically used to flag a value of the dependent variable y that is "illegal" in some way (e.g., negative where only a non-negative value is physically meaningful). If such a return is made, CVODES will attempt to recover (possibly repeating the Newton iteration, or reducing the step size) in order to avoid this recoverable error return.

For efficiency reasons, the right-hand side function is not evaluated at the converged solution of the nonlinear solver. Therefore, in general, a recoverable error in that converged value cannot be corrected. (It may be detected when the right-hand side function is called the first time during the following integration step, but a successful step cannot be undone.) However, if the user program also includes quadrature integration, the state variables can be checked for legality in the call to CVQuadRhsFn, which is called at the converged solution of the nonlinear system, and therefore CVODES can be flagged to attempt to recover from such a situation. Also, if sensitivity analysis is performed with one of the staggered methods, the ODE right-hand side function is called at the converged solution of the nonlinear system, and a recoverable error at that point can be flagged, and CVODES will then try to correct it.

There are two other situations in which recovery is not possible even if the right-hand side function returns a recoverable error flag. One is when this occurs at the very first call to the CVRhsFn (in which case CVODES returns CV\_FIRST\_RHSFUNC\_ERR). The other is when a recoverable error is reported by CVRhsFn after an error test failure, while the linear multistep method order is equal to 1 (in which case CVODES returns CV\_UNREC\_RHSFUNC\_ERR).

#### 4.6.2 Error message handler function

As an alternative to the default behavior of directing error and warning messages to the file pointed to by errfp (see CVodeSetErrFile), the user may provide a function of type CVErrHandlerFn to process any such messages. The function type CVErrHandlerFn is defined as follows:

```
CVErrHandlerFn
```

```
Definition typedef void (*CVErrHandlerFn)(int error_code, const char *module, const char *function, char *msg, void *eh_data);
```

Purpose This function processes error and warning messages from CVODES and its sub-modules.

Arguments error\_code is the error code.

module is the name of the CVODES module reporting the error. function is the name of the function in which the error occurred.

msg is the error message.

eh\_data is a pointer to user data, the same as the eh\_data parameter passed to

CVodeSetErrHandlerFn.

Return value A CVErrHandlerFn function has no return value.

Notes  $\ensuremath{\mathsf{error\_code}}$  is negative for errors and positive (CV\_WARNING) for warnings. If a function

that returns a pointer to memory encounters an error, it sets error\_code to 0.

## 4.6.3 Error weight function

As an alternative to providing the relative and absolute tolerances, the user may provide a function of type CVEwtFn to compute a vector ewt containing the weights in the WRMS norm  $||v||_{WRMS} = \sqrt{(1/N)\sum_{i=1}^{N}(W_i \cdot v_i)^2}$ . These weights will be used in place of those defined by Eq. (2.7). The function type CVEwtFn is defined as follows:

#### CVEwtFn

Definition typedef int (\*CVEwtFn)(N\_Vector y, N\_Vector ewt, void \*user\_data);

Purpose This function computes the WRMS error weights for the vector y.

Arguments y is the value of the dependent variable vector at which the weight vector is

to be computed.

ewt is the output vector containing the error weights.

user\_data is a pointer to user data, the same as the user\_data parameter passed to

CVodeSetUserData.

Return value A CVEwtFn function type must return 0 if it successfully set the error weights and -1

otherwise.

Notes Allocation of memory for ewt is handled within CVODES.

The error weight vector must have all components positive. It is the user's responsibility to perform this test and return -1 if it is not satisfied.

#### 4.6.4 Rootfinding function

If a rootfinding problem is to be solved during the integration of the ODE system, the user must supply a C function of type CVRootFn, defined as follows:

#### CVRootFn

Definition typedef int (\*CVRootFn)(realtype t, N\_Vector y, realtype \*gout, void \*user\_data);

Purpose This function implements a vector-valued function g(t,y) such that the roots of the

**nrtfn** components  $g_i(t, y)$  are sought.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t). gout is the output array, of length nrtfn, with components  $g_i(t, y)$ .

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

Return value A CVRootFn should return 0 if successful or a non-zero value if an error occurred (in which case the integration is halted and CVode returns CV\_RTFUNC\_FAIL).

Notes Allocation of memory for gout is automatically handled within CVODES.

Α

#### 4.6.5 Jacobian information (direct method Jacobian)

If the direct linear solver interface is used (i.e., CVDlsSetLinearSolver is called in the steps described in §4.4), the user may provide a function of type CVDlsJacFn defined as follows:

#### CVDlsJacFn

Definition typedef (\*CVDlsJacFn)(realtype t, N\_Vector y, N\_Vector fy, SUNMatrix Jac, void \*user\_data, N\_Vector tmp1, N\_Vector tmp2, N\_Vector tmp3);

Purpose This function computes the Jacobian matrix  $J = \partial f/\partial y$  (or an approximation to it).

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, namely the predicted value of y(t).

fy is the current value of the vector f(t, y).

Jac is the output Jacobian matrix (of type SUNMatrix).

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

tmp1

tmp2

tmp3 are pointers to memory allocated for variables of type N\_Vector which can be used by a CVDlsJacFn function as temporary storage or work space.

Return value A CVDlsJacFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct, while CVDLS sets last\_flag to CVDLS\_JACFUNC\_RECVR), or a negative value if it failed unrecoverably (in which case the integration is halted, CVodes returns CV\_LSETUP\_FAIL and CVDLS sets last\_flag to CVDLS\_JACFUNC\_UNRECVR).

Notes

Information regarding the structure of the specific SUNMATRIX structure (e.g. number of rows, upper/lower bandwidth, sparsity type) may be obtained through using the implementation-specific SUNMATRIX interface functions (see Chapter 8 for details).

Prior to calling the user-supplied Jacobian function, the Jacobian matrix J(t, y) is zeroed out, so only nonzero elements need to be loaded into Jac.

If the user's CVDlsJacFn function uses difference quotient approximations, then it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv\_mem to user\_data and then use the CVodeGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

#### dense:

A user-supplied dense Jacobian function must load the N by N dense matrix Jac with an approximation to the Jacobian matrix J(t,y) at the point (t,y). The accessor macros SM\_ELEMENT\_D and SM\_COLUMN\_D allow the user to read and write dense matrix elements without making explicit references to the underlying representation of the SUNMATRIX\_DENSE type. SM\_ELEMENT\_D(J, i, j) references the (i, j)-th element of the dense matrix Jac (with i, j = 0...N-1). This macro is meant for small problems for which efficiency of access is not a major concern. Thus, in terms of the indices m and n ranging from 1 to N, the Jacobian element  $J_{m,n}$  can be set using the statement SM\_ELEMENT\_D(J, m-1, n-1) =  $J_{m,n}$ . Alternatively, SM\_COLUMN\_D(J, j) returns a pointer to the first element of the j-th column of Jac (with j = 0...N-1), and the elements of the j-th column can then be accessed using ordinary array indexing. Consequently,  $J_{m,n}$  can be loaded using the statements col\_n = SM\_COLUMN\_D(J, n-1); col\_n[m-1] =  $J_{m,n}$ . For large problems, it is more efficient to use SM\_COLUMN\_D than to

use SM\_ELEMENT\_D. Note that both of these macros number rows and columns starting from 0. The SUNMATRIX\_DENSE type and accessor macros are documented in §8.1.

#### banded:

A user-supplied banded Jacobian function must load the N by N banded matrix Jac with the elements of the Jacobian J(t,y) at the point (t,y). The accessor macros SM\_ELEMENT\_B, SM\_COLUMN\_B, and SM\_COLUMN\_ELEMENT\_B allow the user to read and write band matrix elements without making specific references to the underlying representation of the SUNMATRIX\_BAND type. SM\_ELEMENT\_B(J, i, j) references the (i, j)-th element of the band matrix Jac, counting from 0. This macro is meant for use in small problems for which efficiency of access is not a major concern. Thus, in terms of the indices m and n ranging from 1 to N with (m,n) within the band defined by mupper and mlower, the Jacobian element  $J_{m,n}$  can be loaded using the statement SM\_ELEMENT\_B(J, m-1, n-1) =  $J_{m,n}$ . The elements within the band are those with -mupper  $\leq$  m-n  $\leq$ mlower. Alternatively, SM\_COLUMN\_B(J, j) returns a pointer to the diagonal element of the j-th column of Jac, and if we assign this address to realtype \*col\_j, then the i-th element of the j-th column is given by SM\_COLUMN\_ELEMENT\_B(col\_j, i, j), counting from 0. Thus, for (m,n) within the band,  $J_{m,n}$  can be loaded by setting col\_n = SM\_COLUMN\_B(J, n-1); SM\_COLUMN\_ELEMENT\_B(col\_n, m-1, n-1) =  $J_{m.n}$ . The elements of the j-th column can also be accessed via ordinary array indexing, but this approach requires knowledge of the underlying storage for a band matrix of type SUN-MATRIX\_BAND. The array col\_n can be indexed from -mupper to mlower. For large problems, it is more efficient to use SM\_COLUMN\_B and SM\_COLUMN\_ELEMENT\_B than to use the SM\_ELEMENT\_B macro. As in the dense case, these macros all number rows and columns starting from 0. The SUNMATRIX\_BAND type and accessor macros are documented in  $\S 8.2$ .

#### sparse:

A user-supplied sparse Jacobian function must load the N by N compressed-sparse-column or compressed-sparse-row matrix Jac with an approximation to the Jacobian matrix J(t,y) at the point (t,y). Storage for Jac already exists on entry to this function, although the user should ensure that sufficient space is allocated in Jac to hold the nonzero values to be set; if the existing space is insufficient the user may reallocate the data and index arrays as needed. The amount of allocated space in a Sunmatrix\_sparse object may be accessed using the macro SM\_NNZ\_S or the routine SUNSparseMatrix\_NNZ. The SUNMATRIX\_SPARSE type and accessor macros are documented in §8.3.

# 4.6.6 Jacobian information (matrix-vector product)

If the CVSPILS solver interface is selected (i.e., CVSpilsSetLinearSolver is called in the steps described in  $\S4.4$ ), the user may provide a function of type CVSpilsJacTimesVecFn in the following form, to compute matrix-vector products Jv. If such a function is not supplied, the default is a difference quotient approximation to these products.

```
CVSpilsJacTimesVecFn
Definition
             typedef int (*CVSpilsJacTimesVecFn)(N_Vector v, N_Vector Jv,
                                                       realtype t, N_Vector y, N_Vector fy,
                                                       void *user_data, N_Vector tmp);
             This function computes the product Jv = (\partial f/\partial y)v (or an approximation to it).
Purpose
Arguments
                         is the vector by which the Jacobian must be multiplied.
             V
             Jν
                         is the output vector computed.
                         is the current value of the independent variable.
             t
                         is the current value of the dependent variable vector.
             у
```

is the current value of the vector f(t, y). fy

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

is a pointer to memory allocated for a variable of type N\_Vector which can tmp be used for work space.

Return value The value returned by the Jacobian-vector product function should be 0 if successful. Any other return value will result in an unrecoverable error of the generic Krylov solver,

in which case the integration is halted.

This function must return a value of J \* v that uses the *current* value of J, i.e. as evaluated at the current (t, y).

If the user's CVSpilsJacTimesVecFn function uses difference quotient approximations, it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv\_mem to user\_data and then use the CVodeGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

#### 4.6.7 Jacobian information (matrix-vector setup)

If the user's Jacobian-times-vector requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied function of type CVSpilsJacTimesSetupFn, defined as follows:

#### CVSpilsJacTimesSetupFn

typedef int (\*CVSpilsJacTimesSetupFn)(realtype t, N\_Vector y, Definition N\_Vector fy, void \*user\_data);

This function preprocesses and/or evaluates Jacobian-related data needed by the Jacobian-Purpose times-vector routine.

Arguments is the current value of the independent variable. t.

> is the current value of the dependent variable vector. V

is the current value of the vector f(t, y). fv

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

Return value The value returned by the Jacobian-vector setup function should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

> Each call to the Jacobian-vector setup function is preceded by a call to the CVRhsFn user function with the same (t,y) arguments. Thus, the setup function can use any auxiliary data that is computed and saved during the evaluation of the ODE right-hand side.

> If the user's CVSpilsJacTimesSetupFn function uses difference quotient approximations, it may need to access quantities not in the argument list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv\_mem to user\_data and then use the CVodeGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

#### Preconditioning (linear system solution) 4.6.8

If preconditioning is used, then the user must provide a function to solve the linear system Pz = r, where P may be either a left or right preconditioner matrix. Here P should approximate (at least crudely) the Newton matrix  $M = I - \gamma J$ , where  $J = \partial f/\partial y$ . If preconditioning is done on both sides,

Notes

Notes

the product of the two preconditioner matrices should approximate M. This function must be of type CVSpilsPrecSolveFn, defined as follows:

```
CVSpilsPrecSolveFn
Definition
              typedef int (*CVSpilsPrecSolveFn) (realtype t, N_Vector y, N_Vector fy,
                                                      N_Vector r, N_Vector z, realtype gamma,
                                                      realtype delta, int lr, void *user_data);
              This function solves the preconditioned system Pz = r.
Purpose
Arguments
                         is the current value of the independent variable.
                         is the current value of the dependent variable vector.
              у
                         is the current value of the vector f(t, y).
              fy
                         is the right-hand side vector of the linear system.
              r
                         is the computed output vector.
              7.
                         is the scalar \gamma appearing in the Newton matrix given by M = I - \gamma J.
              gamma
              delta
                         is an input tolerance to be used if an iterative method is employed in the
                         solution. In that case, the residual vector Res = r - Pz of the system should
                         be made less than delta in the weighted l_2 norm, i.e., \sqrt{\sum_i (Res_i \cdot ewt_i)^2} <
                         delta. To obtain the N_Vector ewt, call CVodeGetErrWeights (see §4.5.8.2).
                         is an input flag indicating whether the preconditioner solve function is to
              lr
                         use the left preconditioner (lr = 1) or the right preconditioner (lr = 2);
              user_data is a pointer to user data, the same as the user_data parameter passed to
                         the function CVodeSetUserData.
```

Return value The value returned by the preconditioner solve function is a flag indicating whether it was successful. This value should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

#### 4.6.9 Preconditioning (Jacobian data)

If the user's preconditioner requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied function of type CVSpilsPrecSetupFn, defined as follows:

CVSpilsPre	ecSetupFn					
Definition	typedef	<pre>int (*CVSpilsPrecSetupFn)(realtype t, N_Vector y, N_Vector fy,</pre>				
Purpose	This function	nction preprocesses and/or evaluates Jacobian-related data needed by the pre- oner.				
Arguments	t	is the current value of the independent variable.				
	У	is the current value of the dependent variable vector, namely the predicted value of $y(t)$ .				
	fy	is the current value of the vector $f(t, y)$ .				
	jok	is an input flag indicating whether the Jacobian-related data needs to be updated. The jok argument provides for the reuse of Jacobian data in the preconditioner solve function. jok = SUNFALSE means that the Jacobian-related data must be recomputed from scratch. jok = SUNTRUE means that the Jacobian data, if saved from the previous call to this function, can be reused (with the current value of gamma). A call with jok = SUNTRUE can only occur after a call with jok = SUNFALSE.				

is a pointer to a flag which should be set to SUNTRUE if Jacobian data was icurPtr recomputed, or set to SUNFALSE if Jacobian data was not recomputed, but

saved data was still reused.

is the scalar  $\gamma$  appearing in the Newton matrix  $M = I - \gamma J$ . gamma

user\_data is a pointer to user data, the same as the user\_data parameter passed to the function CVodeSetUserData.

Return value The value returned by the preconditioner setup function is a flag indicating whether it was successful. This value should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

Notes

The operations performed by this function might include forming a crude approximate Jacobian and performing an LU factorization of the resulting approximation to M= $I - \gamma J$ .

Each call to the preconditioner setup function is preceded by a call to the CVRhsFn user function with the same (t,y) arguments. Thus, the preconditioner setup function can use any auxiliary data that is computed and saved during the evaluation of the ODE right-hand side.

This function is not called in advance of every call to the preconditioner solve function, but rather is called only as often as needed to achieve convergence in the Newton iteration.

If the user's CVSpilsPrecSetupFn function uses difference quotient approximations, it may need to access quantities not in the call list. These include the current step size, the error weights, etc. To obtain these, the user will need to add a pointer to cv\_mem to user\_data and then use the CVodeGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

#### 4.7 Integration of pure quadrature equations

CVODES allows the ODE system to include pure quadratures. In this case, it is more efficient to treat the quadratures separately by excluding them from the nonlinear solution stage. To do this, begin by excluding the quadrature variables from the vector y and excluding the quadrature equations from within res. Thus a separate vector yQ of quadrature variables is to satisfy  $(d/dt)yQ = f_O(t,y)$ . The following is an overview of the sequence of calls in a user's main program in this situation. Steps that are unchanged from the skeleton program presented in §4.4 are grayed out.

1. Initialize parallel or multi-threaded environment, if appropriate

#### 2. Set problem dimensions, etc.

Set the problem size N (excluding quadrature variables), and the number of quadrature variables

If appropriate, set the local vector length Nlocal (excluding quadrature variables), and the local number of quadrature variables Nqlocal.

- 3. Set vector of initial values
- 4. Create CVODES object
- 5. Allocate internal memory
- 6. Set optional inputs
- 7. Attach linear solver module

#### 8. Set linear solver optional inputs

#### 9. Set vector yQ0 of initial values for quadrature variables

Typically, the quadrature variables should be initialized to 0.

#### 10. Initialize quadrature integration

Call CVodeQuadInit to specify the quadrature equation right-hand side function and to allocate internal memory related to quadrature integration. See §4.7.1 for details.

#### 11. Set optional inputs for quadrature integration

Call CVodeSetQuadErrCon to indicate whether or not quadrature variables shoule be used in the step size control mechanism, and to specify the integration tolerances for quadrature variables. See §4.7.4 for details.

12. Advance solution in time

#### 13. Extract quadrature variables

Call CVodeGetQuad to obtain the values of the quadrature variables at the current time. See  $\S4.7.3$  for details.

14. Get optional outputs

#### 15. Get quadrature optional outputs

Call CVodeGetQuad\* functions to obtain optional output related to the integration of quadratures. See §4.7.5 for details.

#### 16. Deallocate memory for solution vector and for the vector of quadrature variables

- 17. Free solver memory
- 18. Finalize MPI, if used

CVodeQuadInit can be called and quadrature-related optional inputs (step 11 above) can be set anywhere between steps 4 and 12.

#### 4.7.1 Quadrature initialization and deallocation functions

The function CVodeQuadInit activates integration of quadrature equations and allocates internal memory related to these calculations. The form of the call to this function is as follows:

CVodeQuadI	nit				
Call	flag = CVodeQuadInit(cvode_mem, fQ, yQ0);				
Description	The function CVodeQuadInit provides required problem specifications, allocates internal memory, and initializes quadrature integration.				
Arguments	fQ	(void *) pointer to the CVODES memory block returned by CVodeCreate. (CVQuadRhsFn) is the C function which computes $f_Q$ , the right-hand side of the quadrature equations. This function has the form fQ(t, y, yQdot, fQ_data) (for full details see §4.7.6).			
	уQО	(N_Vector) is the initial value of yQ.			
Return value	value. The return value flag (of type int) will be one of the following:				

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeQuadInit was successful.

CV\_MEM\_NULL The CVODES memory was not initialized by a prior call to CVodeCreate. CV\_MEM\_FAIL A memory allocation request failed.

Notes If an error occurred, CVodeQuadInit also sends an error message to the error handler function.

In terms of the number of quadrature variables  $N_q$  and maximum method order maxord, the size of the real workspace is increased as follows:

- Base value: lenrw = lenrw + (maxord+5) $N_q$
- If using CVodeSVtolerances (see CVodeSetQuadErrCon): lenrw = lenrw  $+N_q$

the size of the integer workspace is increased as follows:

- Base value: leniw = leniw + (maxord+5) $N_q$
- ullet If using CVodeSVtolerances: leniw = leniw  $+N_q$

The function CVodeQuadReInit, useful during the solution of a sequence of problems of same size, reinitializes the quadrature-related internal memory and must follow a call to CVodeQuadInit (and maybe a call to CVodeQuadInit). The number Nq of quadratures is assumed to be unchanged from the prior call to CVodeQuadInit. The call to the CVodeQuadReInit function has the following form:

#### CVodeQuadReInit

Call flag = CVodeQuadReInit(cvode\_mem, yQ0);

Description The function CVodeQuadReInit provides required problem specifications and reinitializes the quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

yQ0 (N\_Vector) is the initial value of yQ.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeReInit was successful.

CV\_MEM\_NULL The CVODES memory was not initialized by a prior call to CVodeCreate.

CV\_NO\_QUAD Memory space for the quadrature integration was not allocated by a prior call to CVodeQuadInit.

Notes

If an error occurred, CVodeQuadReInit also sends an error message to the error handler function.

#### CVodeQuadFree

Call CVodeQuadFree(cvode\_mem);

Description The function CVodeQuadFree frees the memory allocated for quadrature integration.

Arguments The argument is the pointer to the CVODES memory block (of type void \*).

Return value The function CVodeQuadFree has no return value.

Notes In general, CVodeQuadFree need not be called by the user as it is invoked automatically by CVodeFree.

#### 4.7.2 CVODES solver function

Even if quadrature integration was enabled, the call to the main solver function CVode is exactly the same as in §4.5.5. However, in this case the return value flag can also be one of the following:

CV\_QRHSFUNC\_FAIL The quadrature right-hand side function failed in an unrecoverable manner.

CV\_FIRST\_QRHSFUNC\_FAIL The quadrature right-hand side function failed at the first call.

CV\_REPTD\_QRHSFUNC\_ERR Convergence test failures occurred too many times due to repeated recov-

erable errors in the quadrature right-hand side function. This value will also be returned if the quadrature right-hand side function had repeated recoverable errors during the estimation of an initial step size (assuming

the quadrature variables are included in the error tests).

CV\_UNREC\_RHSFUNC\_ERR The quadrature right-hand function had a recoverable error, but no recov-

ery was possible. This failure mode is rare, as it can occur only if the quadrature right-hand side function fails recoverably after an error test

failed while at order one.

## 4.7.3 Quadrature extraction functions

If quadrature integration has been initialized by a call to  ${\tt CVodeQuadInit}$ , or reinitialized by a call to  ${\tt CVodeQuadReInit}$ , then  ${\tt CVODES}$  computes both a solution and quadratures at time t. However,  ${\tt CVode}$  will still return only the solution y in yout. Solution quadratures can be obtained using the following function:

#### ${\tt CVodeGetQuad}$

Call flag = CVodeGetQuad(cvode\_mem, &tret, yQ);

 $\label{prop:condect} \textbf{Description} \quad \text{The function $\tt CVodeGetQuad $\tt returns $\tt the quadrature solution $\tt vector after a successful {\tt returns the quadrature solution } \\ \textbf{The function $\tt CVodeGetQuad $\tt returns the quadrature solution $\tt vector after a successful {\tt returns the quadrature solution } \\ \textbf{The function $\tt CVodeGetQuad $\tt returns the quadrature solution $\tt vector after a successful {\tt returns the quadrature solution } \\ \textbf{The function $\tt CVodeGetQuad $\tt returns the quadrature solution $\tt vector after a successful {\tt returns the quadrature solution } \\ \textbf{The function $\tt CVodeGetQuad $\tt returns the quadrature solution $\tt vector after a successful {\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt cVodeGetQuad $\tt returns the quadrature solution } \\ \textbf{The function $\tt cVodeGetQuad $\tt cVode$ 

return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

tret (realtype) the time reached by the solver (output).

yQ (N\_Vector) the computed quadrature vector.

Return value The return value flag of CVodeGetQuad is one of:

CV\_SUCCESS CVodeGetQuad was successful.

 ${\tt CV\_MEM\_NULL}$  cvode\_mem was  ${\tt NULL}$ .

CV\_NO\_QUAD Quadrature integration was not initialized.

CV\_BAD\_DKY yQ is NULL.

Notes In case of an error return, an error message is also sent to the error handler function.

The function CVodeGetQuadDky computes the k-th derivatives of the interpolating polynomials for the quadrature variables at time t. This function is called by CVodeGetQuad with k=0 and with the current time at which CVode has returned, but may also be called directly by the user.

#### CVodeGetQuadDky

Call flag = CVodeGetQuadDky(cvode\_mem, t, k, dkyQ);

Description The function CVodeGetQuadDky returns derivatives of the quadrature solution vector

after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

t (realtype) the time at which quadrature information is requested. The time t must fall within the interval defined by the last successful step taken

by CVODES.

k (int) order of the requested derivative. This must be  $\leq$  qlast.

dkyQ (N\_Vector) the vector containing the derivative. This vector must be allo-

cated by the user.

Return value The return value flag of CVodeGetQuadDky is one of:

 ${\tt CV\_SUCCESS} \quad {\tt CVodeGetQuadDky} \ {\tt succeeded}.$ 

CV\_MEM\_NULL The pointer to cvode\_mem was NULL.

CV BAD T

CV\_NO\_QUAD Quadrature integration was not initialized.

CV\_BAD\_DKY The vector dkyQ is NULL.

CV\_BAD\_K k is not in the range  $0, 1, \ldots, qlast$ .

Notes In case of an error return, an error message is also sent to the error handler function.

The time t is not in the allowed range.

#### 4.7.4 Optional inputs for quadrature integration

CVODES provides the following optional input functions to control the integration of quadrature equations.

#### CVodeSetQuadErrCon

flag = CVodeSetQuadErrCon(cvode\_mem, errconQ); Call

Description The function CVodeSetQuadErrCon specifies whether or not the quadrature variables are to be used in the step size control mechanism within CVODES. If they are, the user must

call CVodeQuadSStolerances or CVodeQuadSVtolerances to specify the integration

tolerances for the quadrature variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

(booleantype) specifies whether quadrature variables are included (SUNTRUE)

or not (SUNFALSE) in the error control mechanism.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_QUAD Quadrature integration has not been initialized.

Notes By default, errconQ is set to SUNFALSE.

It is illegal to call CVodeSetQuadErrCon before a call to CVodeQuadInit.

If the quadrature variables are part of the step size control mechanism, one of the following functions must be called to specify the integration tolerances for quadrature variables.

#### CVodeQuadSStolerances

flag = CVodeQuadSVtolerances(cvode\_mem, reltolQ, abstolQ); Call

Description The function CVodeQuadSStolerances specifies scalar relative and absolute tolerances.

cvode\_mem (void \*) pointer to the CVODES memory block. Arguments

> reltolQ (realtype) is the scalar relative error tolerance.

(realtype) is the scalar absolute error tolerance. abstolQ

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set. CV\_NO\_QUAD Quadrature integration was not initialized.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT One of the input tolerances was negative.

#### CVodeQuadSVtolerances

Call flag = CVodeQuadSVtolerances(cvode\_mem, reltolQ, abstolQ);

Description The function CVodeQuadSVtolerances specifies scalar relative and vector absolute tol-

erances.

cvode\_mem (void \*) pointer to the CVODES memory block. Arguments

reltolQ (realtype) is the scalar relative error tolerance.
abstolQ (N\_Vector) is the vector absolute error tolerance.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set. CV\_NO\_QUAD Quadrature integration was not initialized.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_ILL\_INPUT One of the input tolerances was negative.

## 4.7.5 Optional outputs for quadrature integration

CVODES provides the following functions that can be used to obtain solver performance information related to quadrature integration.

#### ${\tt CVodeGetQuadNumRhsEvals}$

Call flag = CVodeGetQuadNumRhsEvals(cvode\_mem, &nfQevals);

Description The function CVodeGetQuadNumRhsEvals returns the number of calls made to the user's

quadrature right-hand side function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfQevals (long int) number of calls made to the user's fQ function.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

 ${\tt CV\_NO\_QUAD} \quad {\tt Quadrature\ integration\ has\ not\ been\ initialized}.$ 

#### CVodeGetQuadNumErrTestFails

Call flag = CVodeGetQuadNumErrTestFails(cvode\_mem, &nQetfails);

Description The function CVodeGetQuadNumErrTestFails returns the number of local error test

failures due to quadrature variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nQetfails (long int) number of error test failures due to quadrature variables.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_QUAD Quadrature integration has not been initialized.

#### CVodeGetQuadErrWeights

Call flag = CVodeGetQuadErrWeights(cvode\_mem, eQweight);

Description The function CVodeGetQuadErrWeights returns the quadrature error weights at the

current time.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

eQweight (N\_Vector) quadrature error weights at the current time.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

 ${\tt CV\_MEM\_NULL}$  The  ${\tt cvode\_mem}$  pointer is NULL.

CV\_NO\_QUAD Quadrature integration has not been initialized.

Notes

The user must allocate memory for eQweight.

If quadratures were not included in the error control mechanism (through a call to CVodeSetQuadErrCon with errconQ = SUNTRUE), CVodeGetQuadErrWeights does not set the eQweight vector.

#### CVodeGetQuadStats

Call flag = CVodeGetQuadStats(cvode\_mem, &nfQevals, &nQetfails);

Description The function CVodeGetQuadStats returns the CVODES integrator statistics as a group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfQevals (long int) number of calls to the user's fQ function.

nQetfails (long int) number of error test failures due to quadrature variables.

Return value The return value flag (of type int) is one of

CV\_SUCCESS the optional output values have been successfully set.

CV\_MEM\_NULL the cvode\_mem pointer is NULL.

CV\_NO\_QUAD Quadrature integration has not been initialized.

## 4.7.6 User-supplied function for quadrature integration

For integration of quadrature equations, the user must provide a function that defines the right-hand side of the quadrature equations (in other words, the integrand function of the integral that must be evaluated). This function must be of type CVQuadRhsFn defined as follows:

#### CVQuadRhsFn

Definition typedef int (\*CVQuadRhsFn)(realtype t, N\_Vector y,

N\_Vector yQdot, void \*user\_data);

Purpose This function computes the quadrature equation right-hand side for a given value of the

independent variable t and state vector y.

Arguments t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t).

yQdot is the output vector  $f_Q(t, y)$ .

user\_data is the user\_data pointer passed to CVodeSetUserData.

Return value A CVQuadRhsFn should return 0 if successful, a positive value if a recoverable error oc-

curred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CV\_QRHSFUNC\_FAIL is re-

turned).

Notes Allocation of memory for yQdot is automatically handled within CVODES.

Both y and yQdot are of type N\_Vector, but they typically have different internal representations. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with respect to their N\_Vector arguments (see §7.1 and §7.2).

There are two situations in which recovery is not possible even if CVQuadRhsFn function returns a recoverable error flag. One is when this occurs at the very first call to the CVQuadRhsFn (in which case CVODES returns CV\_FIRST\_QRHSFUNC\_ERR). The other is when a recoverable error is reported by CVQuadRhsFn after an error test failure, while the linear multistep method order is equal to 1 (in which case CVODES returns CV\_UNREC\_QRHSFUNC\_ERR).

#### 4.8 Preconditioner modules

The efficiency of Krylov iterative methods for the solution of linear systems can be greatly enhanced through preconditioning. For problems in which the user cannot define a more effective, problem-specific preconditioner, CVODES provides a banded preconditioner in the module CVBANDPRE and a band-block-diagonal preconditioner module CVBBDPRE.

#### 4.8.1 A serial banded preconditioner module

This preconditioner provides a band matrix preconditioner for use with the CVSPILS iterative linear solver interface, in a serial setting. It uses difference quotients of the ODE right-hand side function f to generate a band matrix of bandwidth  $m_l + m_u + 1$ , where the number of super-diagonals ( $m_u$ , the upper half-bandwidth) and sub-diagonals ( $m_l$ , the lower half-bandwidth) are specified by the user, and uses this to form a preconditioner for use with the Krylov linear solver. Although this matrix is intended to approximate the Jacobian  $\partial f/\partial y$ , it may be a very crude approximation. The true Jacobian need not be banded, or its true bandwidth may be larger than  $m_l + m_u + 1$ , as long as the banded approximation generated here is sufficiently accurate to speed convergence as a preconditioner.

In order to use the CVBANDPRE module, the user need not define any additional functions. Aside from the header files required for the integration of the ODE problem (see §4.3), to use the CVBANDPRE module, the main program must include the header file cvodes\_bandpre.h which declares the needed function prototypes. The following is a summary of the usage of this module. Steps that are unchanged from the skeleton program presented in §4.4 are grayed out.

- 1. Initialize multi-threaded environment, if appropriate
- 2. Set problem dimensions
- 3. Set vector of initial values
- 4. Create CVODES object
- 5. Initialize CVODES solver
- 6. Specify integration tolerances
- 7. Set optional inputs

#### 8. Create linear solver object

When creating the iterative linear solver object, specify the type of preconditioning (PREC\_LEFT or PREC\_RIGHT) to use.

- 9. Set linear solver optional inputs
- 10. Attach linear solver module

#### 11. Initialize the CVBANDPRE preconditioner module

Specify the upper and lower half-bandwidths (mu and ml, respectively) and call

```
flag = CVBandPrecInit(cvode_mem, N, mu, ml);
```

to allocate memory and initialize the internal preconditioner data.

12. Set linear solver interface optional inputs

Note that the user should not overwrite the preconditioner setup function or solve function through calls to the CVSpilsSetPreconditioner optional input function.

13. Specify rootfinding problem

#### 14. Advance solution in time

#### 15. Get optional outputs

Additional optional outputs associated with CVBANDPRE are available by way of two routines described below, CVBandPrecGetWorkSpace and CVBandPrecGetNumRhsEvals.

- 16. Deallocate memory for solution vector
- 17. Free solver memory
- 18. Free linear solver memory

The CVBANDPRE preconditioner module is initialized and attached by calling the following function:

#### CVBandPrecInit

Call flag = CVBandPrecInit(cvode\_mem, N, mu, ml);

Description The function CVBandPrecInit initializes the CVBANDPRE preconditioner and allocates

required (internal) memory for it.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

N (sunindextype) problem dimension.

mu (sunindextype) upper half-bandwidth of the Jacobian approximation.

ml (sunindextype) lower half-bandwidth of the Jacobian approximation.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The call to CVBandPrecInit was successful.

CVSPILS\_MEM\_NULL The cvode\_mem pointer was NULL.

CVSPILS\_MEM\_FAIL A memory allocation request has failed.

CVSPILS\_LMEM\_NULL A CVSPILS linear solver memory was not attached.

CVSPILS\_ILL\_INPUT The supplied vector implementation was not compatible with block band preconditioner.

Notes The banded approximate Jacobian will have nonzero elements only in locations (i, j) with  $-ml \le j - i \le mu$ .

The following three optional output functions are available for use with the CVBANDPRE module:

#### CVBandPrecGetWorkSpace

Notes

Call flag = CVBandPrecGetWorkSpace(cvode\_mem, &lenrwBP, &leniwBP);

Description The function CVBandPrecGetWorkSpace returns the sizes of the CVBANDPRE real and integer workspaces.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

 ${\tt lenrwBP} \quad ({\tt long\ int}) \ {\rm the\ number\ of\ realtype\ values\ in\ the\ CVBANDPRE\ workspace}.$ 

leniwBP (long int) the number of integer values in the CVBANDPRE workspace.

Return value The return value flag (of type int) is one of:

 ${\tt CVSPILS\_SUCCESS} \quad \text{ The optional output values have been successfully set.}$ 

CVSPILS\_PMEM\_NULL The CVBANDPRE preconditioner has not been initialized.

The workspace requirements reported by this routine correspond only to memory allocated within the CVBANDPRE module (the banded matrix approximation, banded SUNLINSOL object, and temporary vectors).

The workspaces referred to here exist in addition to those given by the corresponding function CVSpilsGetWorkSpace.

#### CVBandPrecGetNumRhsEvals

Call flag = CVBandPrecGetNumRhsEvals(cvode\_mem, &nfevalsBP);

Description The function CVBandPrecGetNumRhsEvals returns the number of calls made to the

user-supplied right-hand side function for the finite difference banded Jacobian approx-

imation used within the preconditioner setup function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfevalsBP (long int) the number of calls to the user right-hand side function.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_PMEM\_NULL The CVBANDPRE preconditioner has not been initialized.

Notes The counter nfevalsBP is distinct from the counter nfevalsLS returned by the corre-

sponding function CVSpilsGetNumRhsEvals and nfevals returned by CVodeGetNumRhsEvals.

The total number of right-hand side function evaluations is the sum of all three of these

counters.

#### 4.8.2 A parallel band-block-diagonal preconditioner module

A principal reason for using a parallel ODE solver such as CVODES lies in the solution of partial differential equations (PDEs). Moreover, the use of a Krylov iterative method for the solution of many such problems is motivated by the nature of the underlying linear system of equations (2.5) that must be solved at each time step. The linear algebraic system is large, sparse, and structured. However, if a Krylov iterative method is to be effective in this setting, then a nontrivial preconditioner needs to be used. Otherwise, the rate of convergence of the Krylov iterative method is usually unacceptably slow. Unfortunately, an effective preconditioner tends to be problem-specific.

However, we have developed one type of preconditioner that treats a rather broad class of PDE-based problems. It has been successfully used for several realistic, large-scale problems [24] and is included in a software module within the CVODES package. This module works with the parallel vector module NVECTOR\_PARALLEL and is usable with any of the Krylov iterative linear solvers through the CVSPILS interface. It generates a preconditioner that is a block-diagonal matrix with each block being a band matrix. The blocks need not have the same number of super- and sub-diagonals and these numbers may vary from block to block. This Band-Block-Diagonal Preconditioner module is called CVBBDPRE.

One way to envision these preconditioners is to think of the domain of the computational PDE problem as being subdivided into M non-overlapping subdomains. Each of these subdomains is then assigned to one of the M processes to be used to solve the ODE system. The basic idea is to isolate the preconditioning so that it is local to each process, and also to use a (possibly cheaper) approximate right-hand side function. This requires the definition of a new function g(t,y) which approximates the function f(t,y) in the definition of the ODE system (2.1). However, the user may set g=f. Corresponding to the domain decomposition, there is a decomposition of the solution vector y into M disjoint blocks  $y_m$ , and a decomposition of g into blocks  $g_m$ . The block  $g_m$  depends both on  $y_m$  and on components of blocks  $y_{m'}$  associated with neighboring subdomains (so-called ghost-cell data). Let  $\bar{y}_m$  denote  $y_m$  augmented with those other components on which  $g_m$  depends. Then we have

$$g(t,y) = [g_1(t,\bar{y}_1), g_2(t,\bar{y}_2), \dots, g_M(t,\bar{y}_M)]^T$$
(4.1)

and each of the blocks  $g_m(t, \bar{y}_m)$  is uncoupled from the others.

The preconditioner associated with this decomposition has the form

$$P = diag[P_1, P_2, \dots, P_M] \tag{4.2}$$

where

$$P_m \approx I - \gamma J_m \tag{4.3}$$

and  $J_m$  is a difference quotient approximation to  $\partial g_m/\partial y_m$ . This matrix is taken to be banded, with upper and lower half-bandwidths mudq and mldq defined as the number of non-zero diagonals above and below the main diagonal, respectively. The difference quotient approximation is computed using mudq + mldq +2 evaluations of  $g_m$ , but only a matrix of bandwidth mukeep + mlkeep +1 is retained. Neither pair of parameters need be the true half-bandwidths of the Jacobian of the local block of g, if smaller values provide a more efficient preconditioner. The solution of the complete linear system

$$Px = b (4.4)$$

reduces to solving each of the equations

$$P_m x_m = b_m (4.5)$$

and this is done by banded LU factorization of  $P_m$  followed by a banded backsolve.

Similar block-diagonal preconditioners could be considered with different treatments of the blocks  $P_m$ . For example, incomplete LU factorization or an iterative method could be used instead of banded LU factorization.

The CVBBDPRE module calls two user-provided functions to construct P: a required function  ${\tt gloc}$  (of type CVLocalFn) which approximates the right-hand side function  $g(t,y)\approx f(t,y)$  and which is computed locally, and an optional function  ${\tt cfn}$  (of type CVCommFn) which performs all interprocess communication necessary to evaluate the approximate right-hand side g. These are in addition to the user-supplied right-hand side function  ${\tt f.}$  Both functions take as input the same pointer  ${\tt user\_data}$  that is passed by the user to CVodeSetUserData and that was passed to the user's function  ${\tt f.}$  The user is responsible for providing space (presumably within  ${\tt user\_data}$ ) for components of  ${\tt y}$  that are communicated between processes by  ${\tt cfn}$ , and that are then used by  ${\tt gloc}$ , which should not do any communication.

#### CVLocalFn

Definition typedef int (\*CVLocalFn)(sunindextype Nlocal, realtype t, N\_Vector y, N\_Vector glocal, void \*user\_data);

Purpose This gloc function computes g(t,y). It loads the vector glocal as a function of t and

у.

Arguments Nlocal is the local vector length.

t is the value of the independent variable.

y is the dependent variable. glocal is the output vector.

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

Return value A CVLocalFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVode returns CV\_LSETUP\_FAIL).

Notes This function must assume that all interprocess communication of data needed to calculate glocal has already been done, and that this data is accessible within user\_data.

The case where g is mathematically identical to f is allowed.

#### CVCommFn

Definition typedef int (\*CVCommFn)(sunindextype Nlocal, realtype t, N\_Vector y, void \*user\_data);

Purpose This cfn function performs all interprocess communication necessary for the execution

of the gloc function above, using the input vector y.

Arguments Nlocal is the local vector length.

t is the value of the independent variable.

y is the dependent variable.

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

Return value A CVCommFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVode returns CV\_LSETUP\_FAIL).

Notes The cfn function is expected to save communicated data in space defined within the data structure user\_data.

Each call to the cfn function is preceded by a call to the right-hand side function f with the same (t, y) arguments. Thus, cfn can omit any communication done by f if relevant to the evaluation of glocal. If all necessary communication was done in f, then cfn = NULL can be passed in the call to CVBBDPrecInit (see below).

Besides the header files required for the integration of the ODE problem (see §4.3), to use the CVBBDPRE module, the main program must include the header file cvodes\_bbdpre.h which declares the needed function prototypes.

The following is a summary of the proper usage of this module. Steps that are unchanged from the skeleton program presented in §4.4 are grayed out.

- 1. Initialize MPI environment
- 2. Set problem dimensions
- 3. Set vector of initial values
- 4. Create CVODES object
- 5. Initialize CVODES solver
- 6. Specify integration tolerances
- 7. Set optional inputs

#### 8. Create linear solver object

When creating the iterative linear solver object, specify the type of preconditioning (PREC\_LEFT or PREC\_RIGHT) to use.

- 9. Set linear solver optional inputs
- 10. Attach linear solver module

#### 11. Initialize the CVBBDPRE preconditioner module

Specify the upper and lower half-bandwidths mudq and mldq, and mukeep and mlkeep, and call

to allocate memory and initialize the internal preconditioner data. The last two arguments of CVBBDPrecInit are the two user-supplied functions described above.

12. Set linear solver interface optional inputs

Note that the user should not overwrite the preconditioner setup function or solve function through calls to the CVSpilsSetPreconditioner optional input function.

13. Advance solution in time

#### 14. Get optional outputs

Additional optional outputs associated with CVBBDPRE are available by way of two routines described below, CVBBDPrecGetWorkSpace and CVBBDPrecGetNumGfnEvals.

- 15. Deallocate memory for solution vector
- 16. Free solver memory
- 17. Free linear solver memory
- 18. Finalize MPI

The user-callable functions that initialize (step 11 above) or re-initialize the CVBBDPRE preconditioner module are described next.

#### CVBBDPrecInit

Call flag = CVBBDPrecInit(cvode\_mem, local\_N, mudq, mldq, mukeep, mlkeep, dqrely, gloc, cfn);

Description The function CVBBDPrecInit initializes and allocates (internal) memory for the CVBB-DPRE preconditioner.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

local\_N (sunindextype) local vector length.

mudq (sunindextype) upper half-bandwidth to be used in the difference quotient

Jacobian approximation.

mldq (sunindextype) lower half-bandwidth to be used in the difference quotient

Jacobian approximation.

mukeep (sunindextype) upper half-bandwidth of the retained banded approximate

Jacobian block.

mlkeep (sunindextype) lower half-bandwidth of the retained banded approximate

Jacobian block.

dqrely (realtype) the relative increment in components of y used in the difference

quotient approximations. The default is  $dqrely = \sqrt{unit roundoff}$ , which

can be specified by passing dqrely = 0.0.

gloc (CVLocalFn) the C function which computes the approximation  $g(t,y) \approx$ 

f(t,y).

cfn (CVCommFn) the optional C function which performs all interprocess commu-

nication required for the computation of g(t, y).

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The call to CVBBDPrecInit was successful.

CVSPILS\_MEM\_NULL The cvode\_mem pointer was NULL.

 ${\tt CVSPILS\_MEM\_FAIL} \quad {\rm A \ memory \ allocation \ request \ has \ failed}.$ 

CVSPILS\_LMEM\_NULL A CVSPILS linear solver was not attached.

CVSPILS\_ILL\_INPUT The supplied vector implementation was not compatible with block band preconditioner.

Notes

If one of the half-bandwidths mudq or mldq to be used in the difference quotient calculation of the approximate Jacobian is negative or exceeds the value  $local_N-1$ , it is replaced by 0 or  $local_N-1$  accordingly.

The half-bandwidths  $\mathtt{mudq}$  and  $\mathtt{mldq}$  need not be the true half-bandwidths of the Jacobian of the local block of g when smaller values may provide a greater efficiency.

Also, the half-bandwidths mukeep and mlkeep of the retained banded approximate Jacobian block may be even smaller, to reduce storage and computational costs further.

For all four half-bandwidths, the values need not be the same on every processor.

The CVBBDPRE module also provides a reinitialization function to allow solving a sequence of problems of the same size, with the same linear solver choice, provided there is no change in local\_N, mukeep, or mlkeep. After solving one problem, and after calling CVodeReInit to re-initialize CVODES for a subsequent problem, a call to CVBBDPrecReInit can be made to change any of the following: the half-bandwidths mudq and mldq used in the difference-quotient Jacobian approximations, the relative increment dqrely, or one of the user-supplied functions gloc and cfn. If there is a change in any of the linear solver inputs, an additional call to the "Set" routines provided by the SUNLINSOL module, and/or one or more of the corresponding CVSpilsSet\*\*\* functions, must also be made (in the proper order).

#### CVBBDPrecReInit

Call flag = CVBBDPrecReInit(cvode\_mem, mudq, mldq, dqrely);

Description The function CVBBDPrecReInit re-initializes the CVBBDPRE preconditioner.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

mudq (sunindextype) upper half-bandwidth to be used in the difference quotient

Jacobian approximation.

mldq (sunindextype) lower half-bandwidth to be used in the difference quotient

Jacobian approximation.

dqrely (realtype) the relative increment in components of y used in the difference

quotient approximations. The default is  $dqrely = \sqrt{unit roundoff}$ , which

can be specified by passing dqrely = 0.0.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The call to CVBBDPrecReInit was successful.

CVSPILS\_MEM\_NULL The cvode\_mem pointer was NULL.

CVSPILS\_LMEM\_NULL A CVSPILS linear solver memory was not attached.

CVSPILS\_PMEM\_NULL The function CVBBDPrecInit was not previously called.

Notes If one of the half-bandwidths mudq or mldq is negative or exceeds the value  $local_N-1$ ,

it is replaced by 0 or  $local_N-1$  accordingly.

The following two optional output functions are available for use with the CVBBDPRE module:

#### CVBBDPrecGetWorkSpace

Call flag = CVBBDPrecGetWorkSpace(cvode\_mem, &lenrwBBDP, &leniwBBDP);

Description The function CVBBDPrecGetWorkSpace returns the local CVBBDPRE real and integer

workspace sizes.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

lenrwBBDP (long int) local number of realtype values in the CVBBDPRE workspace.

leniwBBDP (long int) local number of integer values in the CVBBDPRE workspace.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer was NULL.

CVSPILS\_PMEM\_NULL The CVBBDPRE preconditioner has not been initialized.

Notes The workspace requirements reported by this routine correspond only to memory

The workspace requirements reported by this routine correspond only to memory allocated within the CVBBDPRE module (the banded matrix approximation, banded SUN-LINSOL object, temporary vectors). These values are local to each process.

The workspaces referred to here exist in addition to those given by the corresponding function CVSpilsGetWorkSpace.

#### CVBBDPrecGetNumGfnEvals

Call flag = CVBBDPrecGetNumGfnEvals(cvode\_mem, &ngevalsBBDP);

Description The function CVBBDPrecGetNumGfnEvals returns the number of calls made to the user-

supplied gloc function due to the finite difference approximation of the Jacobian blocks

used within the preconditioner setup function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

ngevalsBBDP (long int) the number of calls made to the user-supplied gloc function.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The optional output value has been successfully set.

CVSPILS\_MEM\_NULL The cvode\_mem pointer was NULL.

CVSPILS\_PMEM\_NULL The CVBBDPRE preconditioner has not been initialized.

In addition to the ngevalsBBDP gloc evaluations, the costs associated with CVBBDPRE also include nlinsetups LU factorizations, nlinsetups calls to cfn, npsolves banded backsolve calls, and nfevalsLS right-hand side function evaluations, where nlinsetups is an optional CVODES output and npsolves and nfevalsLS are linear solver optional outputs (see §4.5.8).

# Chapter 5

# Using CVODES for Forward Sensitivity Analysis

This chapter describes the use of CVODES to compute solution sensitivities using forward sensitivity analysis. One of our main guiding principles was to design the CVODES user interface for forward sensitivity analysis as an extension of that for IVP integration. Assuming a user main program and user-defined support routines for IVP integration have already been defined, in order to perform forward sensitivity analysis the user only has to insert a few more calls into the main program and (optionally) define an additional routine which computes the right-hand side of the sensitivity systems (2.11). The only departure from this philosophy is due to the CVRhsFn type definition (§4.6.1). Without changing the definition of this type, the only way to pass values of the problem parameters to the ODE right-hand side function is to require the user data structure f\_data to contain a pointer to the array of real parameters p.

CVODES uses various constants for both input and output. These are defined as needed in this chapter, but for convenience are also listed separately in Appendix B.

We begin with a brief overview, in the form of a skeleton user program. Following that are detailed descriptions of the interface to the various user-callable routines and of the user-supplied routines that were not already described in Chapter 4.

# 5.1 A skeleton of the user's main program

The following is a skeleton of the user's main program (or calling program) as an application of CVODES. The user program is to have these steps in the order indicated, unless otherwise noted. For the sake of brevity, we defer many of the details to the later sections. As in §4.4, most steps are independent of the NVECTOR implementation used; where this is not the case, refer to Chapter 7 for specifics. Differences between the user main program in §4.4 and the one below start only at step (13). Steps that are unchanged from the skeleton program presented in §4.4 are grayed out.

First, note that no additional header files need be included for forward sensitivity analysis beyond those for IVP solution ( $\S4.4$ ).

- 1. Initialize parallel or multi-threaded environment, if appropriate
- 2. Set problem dimensions etc.
- 3. Set vector of initial values
- 4. Create CVODES object
- 5. Initialize CVODES
- 6. Specify integration tolerances

- 7. Set optional inputs
- 8. Create matrix object
- 9. Create linear solver object
- 10. Set linear solver optional inputs
- 11. Attach linear solver module
- 12. Initialize quadrature problem, if not sensitivity-dependent

#### 13. Define the sensitivity problem

•Number of sensitivities (required)

Set  $Ns = N_s$ , the number of parameters with respect to which sensitivities are to be computed.

•Problem parameters (optional)

If CVODES is to evaluate the right-hand sides of the sensitivity systems, set p, an array of Np real parameters upon which the IVP depends. Only parameters with respect to which sensitivities are (potentially) desired need to be included. Attach p to the user data structure user\_data. For example, user\_data->p = p;

If the user provides a function to evaluate the sensitivity right-hand side, p need not be specified.

•Parameter list (optional)

If CVODES is to evaluate the right-hand sides of the sensitivity systems, set plist, an array of Ns integers to specify the parameters p with respect to which solution sensitivities are to be computed. If sensitivities with respect to the j-th parameter p[j] are desired  $(0 \le j < Np)$ , set plist<sub>i</sub> = j, for some  $i = 0, ..., N_s - 1$ .

If plist is not specified, CVODES will compute sensitivities with respect to the first Ns parameters; i.e., plist<sub>i</sub> = i ( $i = 0, ..., N_s - 1$ ).

If the user provides a function to evaluate the sensitivity right-hand side, plist need not be specified.

•Parameter scaling factors (optional)

If CVODES is to estimate tolerances for the sensitivity solution vectors (based on tolerances for the state solution vector) or if CVODES is to evaluate the right-hand sides of the sensitivity systems using the internal difference-quotient function, the results will be more accurate if order of magnitude information is provided.

Set pbar, an array of Ns positive scaling factors. Typically, if  $p_i \neq 0$ , the value  $\bar{p}_i = |p_{\text{plist}_i}|$  can be used.

If pbar is not specified, CVODES will use  $\bar{p}_i = 1.0$ .

If the user provides a function to evaluate the sensitivity right-hand side and specifies tolerances for the sensitivity variables, pbar need not be specified.

Note that the names for p, pbar, plist, as well as the field p of user\_data are arbitrary, but they must agree with the arguments passed to CVodeSetSensParams below.

#### 14. Set sensitivity initial conditions

Set the Ns vectors ySO[i] of initial values for sensitivities (for i = 0, ..., Ns -1), using the appropriate functions defined by the particular NVECTOR implementation chosen.

First, create an array of Ns vectors by making the appropriate call

```
yS0 = N_VCloneVectorArray_***(Ns, y0);
```

```
yS0 = N_VCloneVectorArrayEmpty_***(Ns, y0);
```

Here the argument y0 serves only to provide the N\_Vector type for cloning.

Then, for each  $i = 0, \dots, Ns - 1$ , load initial values for the i-th sensitivity vector ySO[i].

#### 15. Activate sensitivity calculations

Call flag = CVodeSensInit or CVodeSensInit1 to activate forward sensitivity computations and allocate internal memory for CVODES related to sensitivity calculations (see §5.2.1).

#### 16. Set sensitivity tolerances

Call CVodeSensSStolerances, CVodeSensSVtolerances or CVodeEEtolerances. (See §5.2.2).

#### 17. Set sensitivity analysis optional inputs

Call CVodeSetSens\* routines to change from their default values any optional inputs that control the behavior of CVODES in computing forward sensitivities. (See §5.2.5.)

- 18. Specify rootfinding
- 19. Advance solution in time

#### 20. Extract sensitivity solution

After each successful return from CVode, the solution of the original IVP is available in the y argument of CVode, while the sensitivity solution can be extracted into yS (which can be the same as ySO) by calling one of the routines CVodeGetSens,CVodeGetSens1, CVodeGetSensDky, or CVodeGetSensDky1 (see §5.2.4).

- 21. Get optional outputs
- 22. Deallocate memory for solution vector

#### 23. Deallocate memory for sensitivity vectors

Upon completion of the integration, deallocate memory for the vectors yS0 using the appropriate destructor:

```
N_VDestroyVectorArray_***(yS0, Ns);
```

If yS was created from realtype arrays yS\_i, it is the user's responsibility to also free the space for the arrays ySO\_i.

#### 24. Free user data structure

- 25. Free solver memory
- 26. Free vector specification memory
- 27. Free linear solver and matrix memory
- 28. Finalize MPI, if used

# 5.2 User-callable routines for forward sensitivity analysis

This section describes the CVODES functions, in addition to those presented in §4.5, that are called by the user to setup and solve a forward sensitivity problem.

## 5.2.1 Forward sensitivity initialization and deallocation functions

Activation of forward sensitivity computation is done by calling CVodeSensInit or CVodeSensInit1, depending on whether the sensitivity right-hand side function returns all sensitivities at once or one by one, respectively. The form of the call to each of these routines is as follows:

#### CVodeSensInit

Call flag = CVodeSensInit(cvode\_mem, Ns, ism, fS, yS0);

Description The routine CVodeSensInit activates forward sensitivity computations and allocates internal memory related to sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

Ns (int) the number of sensitivities to be computed.

ism (int) a flag used to select the sensitivity solution method. Its value can be CV\_SIMULTANEOUS or CV\_STAGGERED:

- In the CV\_SIMULTANEOUS approach, the state and sensitivity variables
  are corrected at the same time. If CV\_NEWTON was selected as the nonlinear system solution method, this amounts to performing a modified
  Newton iteration on the combined nonlinear system;
- In the CV\_STAGGERED approach, the correction step for the sensitivity variables takes place at the same time for all sensitivity equations, but only after the correction of the state variables has converged and the state variables have passed the local error test;

fS (CVSensRhsFn) is the C function which computes all sensitivity ODE right-hand sides at the same time. For full details see §5.3.

ySO (N\_Vector \*) a pointer to an array of Ns vectors containing the initial values of the sensitivities.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSensInit was successful.

 $\begin{array}{ll} {\tt CV\_MEM\_NULL} & {\tt The\ CVODES\ memory\ block\ was\ not\ initialized\ through\ a\ previous\ call} \\ & {\tt to\ CVodeCreate.} \end{array}$ 

CV\_MEM\_FAIL A memory allocation request has failed.

CV\_ILL\_INPUT An input argument to CVodeSensInit has an illegal value.

Notes Passing fS=NULL indicates using the default internal difference quotient sensitivity right-hand side routine.

If an error occurred, CVodeSensInit also sends an error message to the error handler function.

It is illegal here to use  $ism = CV\_STAGGERED1$ . This option requires a different type for fS and can therefore only be used with CVodeSensInit1 (see below).

#### CVodeSensInit1

Call flag = CVodeSensInit1(cvode\_mem, Ns, ism, fS1, yS0);

Description The routine CVodeSensInit1 activates forward sensitivity computations and allocates internal memory related to sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

Ns (int) the number of sensitivities to be computed.

ism (int) a flag used to select the sensitivity solution method. Its value can be CV\_SIMULTANEOUS, CV\_STAGGERED, or CV\_STAGGERED1:

- In the CV\_SIMULTANEOUS approach, the state and sensitivity variables
  are corrected at the same time. If CV\_NEWTON was selected as the nonlinear system solution method, this amounts to performing a modified
  Newton iteration on the combined nonlinear system;
- In the CV\_STAGGERED approach, the correction step for the sensitivity variables takes place at the same time for all sensitivity equations, but only after the correction of the state variables has converged and the state variables have passed the local error test;
- In the CV\_STAGGERED1 approach, all corrections are done sequentially, first for the state variables and then for the sensitivity variables, one parameter at a time. If the sensitivity variables are not included in the error control, this approach is equivalent to CV\_STAGGERED. Note that the CV\_STAGGERED1 approach can be used only if the user-provided sensitivity right-hand side function is of type CVSensRhs1Fn (see §5.3).

fS1 (CVSensRhs1Fn) is the C function which computes the right-hand sides of the sensitivity ODE, one at a time. For full details see §5.3.

ySO (N\_Vector \*) a pointer to an array of Ns vectors containing the initial values of the sensitivities.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSensInit1 was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_MEM\_FAIL A memory allocation request has failed.

CV\_ILL\_INPUT An input argument to CVodeSensInit1 has an illegal value.

Notes

Passing fS1=NULL indicates using the default internal difference quotient sensitivity right-hand side routine.

If an error occurred, CVodeSensInit1 also sends an error message to the error handler function

In terms of the problem size N, number of sensitivity vectors  $N_s$ , and maximum method order maxord, the size of the real workspace is increased as follows:

- Base value: lenrw = lenrw + (maxord+5) $N_sN$
- ullet With CVodeSensSVtolerances: lenrw = lenrw  $+N_sN$

the size of the integer workspace is increased as follows:

- Base value: leniw = leniw + (maxord+5) $N_sN_i$
- With CVodeSensSVtolerances: leniw = leniw  $+N_sN_i$

where  $N_i$  is the number of integers in one N\_Vector.

The routine CVodeSensReInit, useful during the solution of a sequence of problems of same size, reinitializes the sensitivity-related internal memory. The call to it must follow a call to CVodeSensInit or CVodeSensInit1 (and maybe a call to CVodeReInit). The number Ns of sensitivities is assumed to be unchanged since the call to the initialization function. The call to the CVodeSensReInit function has the form:

## CVodeSensReInit

Call flag = CVodeSensReInit(cvode\_mem, ism, yS0);

Description The routine CVodeSensReInit reinitializes forward sensitivity computations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

vS0

(int) a flag used to select the sensitivity solution method. Its value can be ism CV\_SIMULTANEOUS, CV\_STAGGERED, or CV\_STAGGERED1.

(N\_Vector \*) a pointer to an array of Ns variables of type N\_Vector containing the initial values of the sensitivities.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeReInit was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_NO\_SENS Memory space for sensitivity integration was not allocated through a previous call to CVodeSensInit.

CV\_ILL\_INPUT An input argument to CVodeSensReInit has an illegal value.

CV\_MEM\_FAIL A memory allocation request has failed.

All arguments of CVodeSensReInit are the same as those of the functions CVodeSensInit Notes and CVodeSensInit1.

If an error occurred, CVodeSensReInit also sends a message to the error handler func-

The value of the input argument ism must be compatible with the type of the sensitivity ODE right-hand side function. Thus if the sensitivity module was initialized using CVodeSensInit, then it is illegal to pass ism = CV\_STAGGERED1 to CVodeSensReInit.

To deallocate all forward sensitivity-related memory (allocated in a prior call to CVodeSensInit or CVodeSensInit1), the user must call

## CVodeSensFree

Call CVodeSensFree(cvode\_mem);

Description The function CVodeSensFree frees the memory allocated for forward sensitivity computations by a previous call to CVodeSensInit or CVodeSensInit1.

Arguments The argument is the pointer to the CVODES memory block (of type void \*).

Return value The function CVodeSensFree has no return value.

Notes In general, CVodeSensFree need not be called by the user, as it is invoked automatically by CVodeFree.

After a call to CVodeSensFree, forward sensitivity computations can be reactivated only by calling CVodeSensInit or CVodeSensInit1 again.

To activate and deactivate forward sensitivity calculations for successive CVODES runs, without having to allocate and deallocate memory, the following function is provided:

## CVodeSensToggleOff

Call CVodeSensToggleOff(cvode\_mem);

The function CVodeSensToggleOff deactivates forward sensitivity calculations. It does Description not deallocate sensitivity-related memory.

Arguments cvode\_mem (void \*) pointer to the memory previously returned by CVodeCreate.

Return value The return value flag of CVodeSensToggle is one of:

CV\_SUCCESS CVodeSensToggleOff was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

Notes Since sensitivity-related memory is not deallocated, sensitivities can be reactivated at

a later time (using CVodeSensReInit).

## 5.2.2 Forward sensitivity tolerance specification functions

One of the following three functions must be called to specify the integration tolerances for sensitivities. Note that this call must be made after the call to CVodeSensInit/CVodeSensInit1.

## CVodeSensSStolerances

Call flag = CVodeSensSStolerances(cvode\_mem, reltolS, abstolS);

Description The function CVodeSensSStolerances specifies scalar relative and absolute tolerances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

reltolS (realtype) is the scalar relative error tolerance.

abstolS (realtype\*) is a pointer to an array of length Ns containing the scalar

absolute error tolerances, one for each parameter.

Return value The return flag flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSStolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call

to CVodeCreate.

CV\_NO\_SENS The sensitivity allocation function (CVodeSensInit or CVodeSensInit1)

has not been called.

CV\_ILL\_INPUT One of the input tolerances was negative.

#### CVodeSensSVtolerances

Call flag = CVodeSensSVtolerances(cvode\_mem, reltolS, abstolS);

Description The function CVodeSensSVtolerances specifies scalar relative tolerance and vector ab-

solute tolerances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

reltolS (realtype) is the scalar relative error tolerance.

abstolS (N\_Vector\*) is an array of Ns variables of type N\_Vector. The N\_Vector

from abstolS[is] specifies the vector tolerances for is-th sensitivity.

Return value The return flag flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSVtolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call

to CVodeCreate.

CV\_NO\_SENS The allocation function for sensitivities has not been called.

 ${\tt CV\_ILL\_INPUT}$  The relative error tolerance was negative or an absolute tolerance vector

had a negative component.

Notes This choice of tolerances is important when the absolute error tolerance needs to be

different for each component of any vector yS[i].

## CVodeSensEEtolerances

Call flag = CVodeSensEEtolerances(cvode\_mem);

Description When CVodeSensEEtolerances is called, CVODES will estimate tolerances for sensitivity

variables based on the tolerances supplied for states variables and the scaling factors  $\bar{p}$ .

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

Return value The return flag flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSensEEtolerances was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call

to CVodeCreate.

CV\_NO\_SENS The sensitivity allocation function has not been called.

#### **CVODES** solver function 5.2.3

Even if forward sensitivity analysis was enabled, the call to the main solver function CVode is exactly the same as in §4.5.5. However, in this case the return value flag can also be one of the following:

CV\_SRHSFUNC\_FAIL The sensitivity right-hand side function failed in an unrecoverable manner.

CV\_FIRST\_SRHSFUNC\_ERR The sensitivity right-hand side function failed at the first call.

Convergence tests occurred too many times due to repeated recoverable CV\_REPTD\_SRHSFUNC\_ERR errors in the sensitivity right-hand side function. This flag will also be

returned if the sensitivity right-hand side function had repeated recoverable

errors during the estimation of an initial step size.

CV\_UNREC\_SRHSFUNC\_ERR The sensitivity right-hand function had a recoverable error, but no recovery

was possible. This failure mode is rare, as it can occur only if the sensitivity right-hand side function fails recoverably after an error test failed while at

order one.

#### 5.2.4 Forward sensitivity extraction functions

If forward sensitivity computations have been initialized by a call to CVodeSensInit/CVodeSensInit1, or reinitialized by a call to CVSensReInit, then CVODES computes both a solution and sensitivities at time t. However, CVode will still return only the solution y in yout. Solution sensitivities can be obtained through one of the following functions:

## CVodeGetSens

Call flag = CVodeGetSens(cvode\_mem, &tret, yS);

The function CVodeGetSens returns the sensitivity solution vectors after a successful Description

return from CVode.

cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit. Arguments

> tret (realtype \*) the time reached by the solver (output).

(N\_Vector \*) array of computed forward sensitivity vectors. yS

Return value The return value flag of CVodeGetSens is one of:

CV\_SUCCESS CVodeGetSens was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_BAD\_DKY yS is NULL.

Notes Note that the argument tret is an output for this function. Its value will be the same as that returned at the last CVode call.

The function CVodeGetSensDky computes the k-th derivatives of the interpolating polynomials for the sensitivity variables at time t. This function is called by CVodeGetSens with k = 0, but may also be called directly by the user.

#### CVodeGetSensDky

Call flag = CVodeGetSensDky(cvode\_mem, t, k, dkyS);

The function CVodeGetSensDky returns derivatives of the sensitivity solution vectors Description

after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

> (realtype) specifies the time at which sensitivity information is requested. t The time t must fall within the interval defined by the last successful step taken by CVODES.

(int) order of derivatives. k

dkyS (N\_Vector \*) array of Ns vectors containing the derivatives on output. The space for dkyS must be allocated by the user.

Return value The return value flag of CVodeGetSensDky is one of:

CV\_SUCCESS CVodeGetSensDky succeeded.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_BAD\_DKY One of the vectors dkyS is NULL.

 $CV\_BAD\_K$  k is not in the range 0, 1, ..., qlast.

CV\_BAD\_T The time t is not in the allowed range.

Forward sensitivity solution vectors can also be extracted separately for each parameter in turn through the functions CVodeGetSens1 and CVodeGetSensDky1, defined as follows:

## CVodeGetSens1

Call flag = CVodeGetSens1(cvode\_mem, &tret, is, yS);

Description The function CVodeGetSens1 returns the is-th sensitivity solution vector after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

tret (realtype \*) the time reached by the solver (output).

is (int) specifies which sensitivity vector is to be returned  $(0 \le is < N_s)$ .

yS (N\_Vector) the computed forward sensitivity vector.

Return value The return value flag of CVodeGetSens1 is one of:

CV\_SUCCESS CVodeGetSens1 was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_BAD\_IS The index is is not in the allowed range.

CV\_BAD\_DKY vS is NULL.

CV\_BAD\_T The time t is not in the allowed range.

Notes Note that the argument tret is an output for this function. Its value will be the same as that returned at the last CVode call.

## CVodeGetSensDky1

Call flag = CVodeGetSensDky1(cvode\_mem, t, k, is, dkyS);

Description The function CVodeGetSensDky1 returns the k-th derivative of the is-th sensitivity solution vector after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

t (realtype) specifies the time at which sensitivity information is requested.

The time t must fall within the interval defined by the last successful step taken by CVODES.

k (int) order of derivative.

is (int) specifies the sensitivity derivative vector to be returned ( $0 \le i \le N_s$ ).

dkyS (N\_Vector) the vector containing the derivative. The space for dkyS must be allocated by the user.

Return value The return value flag of CVodeGetSensDky1 is one of:

CV\_SUCCESS CVodeGetQuadDky1 succeeded.

CV\_MEM\_NULL The pointer to cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_BAD\_DKY dkyS or one of the vectors dkyS[i] is NULL.

CV\_BAD\_IS The index is is not in the allowed range.

CV\_BAD\_K k is not in the range 0,1,..., qlast.

CV\_BAD\_T The time t is not in the allowed range.

## 5.2.5 Optional inputs for forward sensitivity analysis

Optional input variables that control the computation of sensitivities can be changed from their default values through calls to CVodeSetSens\* functions. Table 5.1 lists all forward sensitivity optional input functions in CVODES which are described in detail in the remainder of this section.

## CVodeSetSensParams

Call flag = CVodeSetSensParams(cvode\_mem, p, pbar, plist);

Description The function CVodeSetSensParams specifies problem parameter information for sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

p (realtype \*) a pointer to the array of real problem parameters used to evaluate f(t, y, p). If non-NULL, p must point to a field in the user's data structure user\_data passed to the right-hand side function. (See §5.1).

pbar (realtype \*) an array of Ns positive scaling factors. If non-NULL, pbar must have all its components > 0.0. (See §5.1).

plist (int \*) an array of Ns non-negative indices to specify which components

p[i] to use in estimating the sensitivity equations. If non-NULL, plist must have all components  $\geq 0$ . (See §5.1).

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_ILL\_INPUT An argument has an illegal value.

Notes

This function must be preceded by a call to CVodeSensInit or CVodeSensInit1.

## CVodeSetSensDQMethod

Call flag = CVodeSetSensDQMethod(cvode\_mem, DQtype, DQrhomax);

Description The function CVodeSetSensDQMethod specifies the difference quotient strategy in the case in which the right-hand side of the sensitivity equations are to be computed by

CVODES.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

DQtype (int) specifies the difference quotient type. Its value can be CV\_CENTERED

or CV\_FORWARD.

Table 5.1: Forward sensitivity optional inputs

Optional input	Routine name	Default
Sensitivity scaling factors	CVodeSetSensParams	NULL
DQ approximation method	CVodeSetSensDQMethod	centered/0.0
Error control strategy	CVodeSetSensErrCon	SUNFALSE
Maximum no. of nonlinear iterations	CVodeSetSensMaxNonlinIters	3

DQrhomax (realtype) positive value of the selection parameter used in deciding switching between a simultaneous or separate approximation of the two terms in the sensitivity right-hand side.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL. CV\_ILL\_INPUT An argument has an illegal value.

Notes

If  $\mathtt{DQrhomax} = 0.0$ , then no switching is performed. The approximation is done simultaneously using either centered or forward finite differences, depending on the value of  $\mathtt{DQtype}$ . For values of  $\mathtt{DQrhomax} \geq 1.0$ , the simultaneous approximation is used whenever the estimated finite difference perturbations for states and parameters are within a factor of  $\mathtt{DQrhomax}$ , and the separate approximation is used otherwise. Note that a value  $\mathtt{DQrhomax} < 1.0$  will effectively disable switching. See §2.6 for more details.

The default value are DQtype=CV\_CENTERED and DQrhomax= 0.0.

## ${\tt CVodeSetSensErrCon}$

Call flag = CVodeSetSensErrCon(cvode\_mem, errconS);

Description The function CVodeSetSensErrCon specifies the error control strategy for sensitivity

variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

errconS (booleantype) specifies whether sensitivity variables are to be included (SUNTRUE) or not (SUNFALSE) in the error control mechanism.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes

By default, errconS is set to SUNFALSE. If errconS=SUNTRUE then both state variables and sensitivity variables are included in the error tests. If errconS=SUNFALSE then the sensitivity variables are excluded from the error tests. Note that, in any event, all variables are considered in the convergence tests.

#### CVodeSetSensMaxNonlinIters

Call flag = CVodeSetSensMaxNonlinIters(cvode\_mem, maxcorS);

Description The function CVodeSetSensMaxNonlinIters specifies the maximum number of nonlin-

ear solver iterations for sensitivity variables per step.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

maxcorS (int) maximum number of nonlinear solver iterations allowed per step (>0).

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

Notes The default value is 3.

## 5.2.6 Optional outputs for forward sensitivity analysis

Optional output functions that return statistics and solver performance information related to forward sensitivity computations are listed in Table 5.2 and described in detail in the remainder of this section.

## CVodeGetSensNumRhsEvals

Call flag = CVodeGetSensNumRhsEvals(cvode\_mem, &nfSevals);

Description The function CVodeGetSensNumRhsEvals returns the number of calls to the sensitivity

right-hand side function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfSevals (long int) number of calls to the sensitivity right-hand side function.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes In order to accommodate any of the three possible sensitivity solution methods, the

default internal finite difference quotient functions evaluate the sensitivity right-hand sides one at a time. Therefore, nfSevals will always be a multiple of the number of sensitivity parameters (the same as the case in which the user supplies a routine of type

CVSensRhs1Fn).

## CVodeGetNumRhsEvalsSens

Call flag = CVodeGetNumRhsEvalsSens(cvode\_mem, &nfevalsS);

Description The function CVodeGetNumRhsEvalsSEns returns the number of calls to the user's right-

hand side function due to the internal finite difference approximation of the sensitivity

right-hand sides.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfevalsS (long int) number of calls to the user's ODE right-hand side function for

the evaluation of sensitivity right-hand sides.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes This counter is incremented only if the internal finite difference approximation routines

are used for the evaluation of the sensitivity right-hand sides.

## CVodeGetSensNumErrTestFails

Call flag = CVodeGetSensNumErrTestFails(cvode\_mem, &nSetfails);

Table 5.2: Forward sensitivity optional outputs

Optional output	Routine name
No. of calls to sensitivity r.h.s. function	CVodeGetSensNumRhsEvals
No. of calls to r.h.s. function for sensitivity	CVodeGetNumRhsEvalsSens
No. of sensitivity local error test failures	CVodeGetSensNumErrTestFails
No. of calls to lin. solv. setup routine for sens.	CVodeGetSensNumLinSolvSetups
Error weight vector for sensitivity variables	CVodeGetSensErrWeights
No. of sens. nonlinear solver iterations	CVodeGetSensNumNonlinSolvIters
No. of sens. convergence failures	CVodeGetSensNumNonlinSolvConvFails
No. of staggered nonlinear solver iterations	CVodeGetStgrSensNumNonlinSolvIters
No. of staggered convergence failures	CVodeGetStgrSensNumNonlinSolvConvFails

Description The function CVodeGetSensNumErrTestFails returns the number of local error test

failures for the sensitivity variables that have occurred.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSetfails (long int) number of error test failures.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes This counter is incremented only if the sensitivity variables have been included in the

error test (see CVodeSetSensErrCon in §5.2.5). Even in that case, this counter is not incremented if the ism=CV\_SIMULTANEOUS sensitivity solution method has been used.

## CVodeGetSensNumLinSolvSetups

Call flag = CVodeGetSensNumLinSolvSetups(cvode\_mem, &nlinsetupsS);

Description The function CVodeGetSensNumLinSolvSetups returns the number of calls to the linear

solver setup function due to forward sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nlinsetupsS (long int) number of calls to the linear solver setup function.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes This counter is incremented only if Newton iteration has been used and if either the

ism = CV\_STAGGERED or the ism = CV\_STAGGERED1 sensitivity solution method has been

specified (see  $\S5.2.1$ ).

## CVodeGetSensStats

Call flag = CVodeGetSensStats(cvode\_mem, &nfSevals, &nfevalsS, &nSetfails, &nSetfails, &nlinsetupsS);

Description The function CVodeGetSensStats returns all of the above sensitivity-related solver

statistics as a group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nfSevals (long int) number of calls to the sensitivity right-hand side function.

nfevalsS (long int) number of calls to the ODE right-hand side function for sensi-

tivity evaluations.

nSetfails (long int) number of error test failures.

nlinsetups (long int) number of calls to the linear solver setup function.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output values have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

## CVodeGetSensErrWeights

Call flag = CVodeGetSensErrWeights(cvode\_mem, eSweight);

Description The function CVodeGetSensErrWeights returns the sensitivity error weight vectors at

the current time. These are the reciprocals of the  $W_i$  of (2.7) for the sensitivity variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

eSweight (N\_Vector \*) pointer to the array of error weight vectors.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes The user must allocate memory for eweights.

## CVodeGetSensNumNonlinSolvIters

Call flag = CVodeGetSensNumNonlinSolvIters(cvode\_mem, &nSniters);

Description The function CVodeGetSensNumNonlinSolvIters returns the number of nonlinear iter-

ations performed for sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSniters (long int) number of nonlinear iterations performed.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes This counter is incremented only if ism was CV\_STAGGERED or CV\_STAGGERED1 (see

§5.2.1).

In the CV\_STAGGERED1 case, the value of nSniters is the sum of the number of nonlinear iterations performed for each sensitivity equation. These individual counters can be obtained through a call to CVodeGetStgrSensNumNonlinSolvIters (see below).

## CVodeGetSensNumNonlinSolvConvFails

Call flag = CVodeGetSensNumNonlinSolvConvFails(cvode\_mem, &nSncfails);

Description The function CVodeGetSensNumNonlinSolvConvFails returns the number of nonlinear

convergence failures that have occurred for sensitivity calculations.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes This counter is incremented only if ism was CV\_STAGGERED or CV\_STAGGERED1 (see

§5.2.1).

In the CV\_STAGGERED1 case, the value of nSncfails is the sum of the number of non-linear convergence failures that occurred for each sensitivity equation. These individual counters can be obtained through a call to CVodeGetStgrSensNumNonlinConvFails (see below).

## CVodeGetSensNonlinSolvStats

Call flag = CVodeGetSensNonlinSolvStats(cvode\_mem, &nSniters, &nSncfails);

Description The function CVodeGetSensNonlinSolvStats returns the sensitivity-related nonlinear

solver statistics as a group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSniters (long int) number of nonlinear iterations performed. nSncfails (long int) number of nonlinear convergence failures.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output values have been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

## ${\tt CVodeGetStgrSensNumNonlinSolvIters}$

Call flag = CVodeGetStgrSensNumNonlinSolvIters(cvode\_mem, nSTGR1niters);

Description The function CVodeGetStgrSensNumNonlinSolvIters returns the number of nonlinear

(functional or Newton) iterations performed for each sensitivity equation separately, in

the CV\_STAGGERED1 case.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSTGR1niters (long int \*) an array (of dimension Ns) which will be set with the number of nonlinear iterations performed for each sensitivity system indi-

vidually.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes The user must allocate space for nSTGR1niters.

#### CVodeGetStgrSensNumNonlinSolvConvFails

Call flag = CVodeGetStgrSensNumNonlinSolvConvFails(cvode\_mem, nSTGR1ncfails);

Description The function CVodeGetStgrSensNumNonlinSolvConvFails returns the number of non-

linear convergence failures that have occurred for each sensitivity equation separately,

in the CV\_STAGGERED1 case.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nSTGR1ncfails (long int \*) an array (of dimension Ns) which will be set with the number of nonlinear convergence failures for each sensitivity system indi-

vidually.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CV\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

Notes The user must allocate space for nSTGR1ncfails.

# 5.3 User-supplied routines for forward sensitivity analysis

In addition to the required and optional user-supplied routines described in §4.6, when using CVODES for forward sensitivity analysis, the user has the option of providing a routine that calculates the right-hand side of the sensitivity equations (2.11).

By default, CVODES uses difference quotient approximation routines for the right-hand sides of the sensitivity equations. However, CVODES allows the option for user-defined sensitivity right-hand side routines (which also provides a mechanism for interfacing CVODES to routines generated by automatic differentiation).

## 5.3.1 Sensitivity equations right-hand side (all at once)

If the CV\_SIMULTANEOUS or CV\_STAGGERED approach was selected in the call to CVodeSensInit or CVodeSensInit1, the user may provide the right-hand sides of the sensitivity equations (2.11), for all sensitivity parameters at once, through a function of type CVSensRhsFn defined by:

## CVSensRhsFn

Purpose This function computes the sensitivity right-hand side for all sensitivity equations at once. It must compute the vectors  $(\partial f/\partial y)s_i(t) + (\partial f/\partial p_i)$  and store them in ySdot[i].

Arguments t is the current value of the independent variable.

y is the current value of the state vector, y(t).

ydot is the current value of the right-hand side of the state equations.

yS contains the current values of the sensitivity vectors.

ySdot is the output of CVSensRhsFn. On exit it must contain the sensitivity right-hand side vectors.

user\_data is a pointer to user data, the same as the user\_data parameter passed to CVodeSetUserData.

tmp1

tmp2 are N-Vectors of length N which can be used as temporary storage.

Return value A CVSensRhsFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CV\_SRHSFUNC\_FAIL is returned).

Notes

A sensitivity right-hand side function of type CVSensRhsFn is not compatible with the CV\_STAGGERED1 approach.

Allocation of memory for ySdot is handled within CVODES.

There are two situations in which recovery is not possible even if CVSensRhsFn function returns a recoverable error flag. One is when this occurs at the very first call to the CVSensRhsFn (in which case CVODES returns CV\_FIRST\_SRHSFUNC\_ERR). The other is when a recoverable error is reported by CVSensRhsFn after an error test failure, while the linear multistep method order is equal to 1 (in which case CVODES returns CV\_UNREC\_SRHSFUNC\_ERR).

#### 5.3.2Sensitivity equations right-hand side (one at a time)

Alternatively, the user may provide the sensitivity right-hand sides, one sensitivity parameter at a time, through a function of type CVSensRhs1Fn. Note that a sensitivity right-hand side function of type CVSensRhs1Fn is compatible with any valid value of the argument ism to CVodeSensInit and CVodeSensInit1, and is required if ism = CV\_STAGGERED1 in the call to CVodeSensInit1. The type CVSensRhs1Fn is defined by

#### CVSensRhs1Fn

Definition typedef int (\*CVSensRhs1Fn)(int Ns, realtype t,

N\_Vector y, N\_Vector ydot,

int iS, N\_Vector yS, N\_Vector ySdot,

void \*user\_data,

N\_Vector tmp1, N\_Vector tmp2);

Purpose

This function computes the sensitivity right-hand side for one sensitivity equation at a time. It must compute the vector  $(\partial f/\partial y)s_i(t) + (\partial f/\partial p_i)$  for i = iS and store it in ySdot.

Arguments

is the current value of the independent variable.

is the current value of the state vector, y(t).

is the current value of the right-hand side of the state equations. ydot

is the index of the parameter for which the sensitivity right-hand side must be iS computed  $(0 \le iS < Ns)$ .

yS contains the current value of the iS-th sensitivity vector.

is the output of CVSensRhs1Fn. On exit it must contain the iS-th sensitivity ySdot

right-hand side vector.

user\_data is a pointer to user data, the same as the user\_data parameter passed to  ${\tt CVodeSetUserData}.$ 

tmp1

tmp2 are  $N_{\text{-}}$ Vectors of length N which can be used as temporary storage.

Return value A CVSensRhs1Fn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CV\_SRHSFUNC\_FAIL is returned).

Notes

Allocation of memory for ySdot is handled within CVODES.

There are two situations in which recovery is not possible even if CVSensRhs1Fn function returns a recoverable error flag. One is when this occurs at the very first call to the CVSensRhs1Fn (in which case CVODES returns CV\_FIRST\_SRHSFUNC\_ERR). The other is when a recoverable error is reported by CVSensRhs1Fn after an error test failure, while the linear multistep method order equal to 1 (in which case CVODES returns CV\_UNREC\_SRHSFUNC\_ERR).

#### Integration of quadrature equations depending on forward 5.4 sensitivities

CVODES provides support for integration of quadrature equations that depends not only on the state variables but also on forward sensitivities.

The following is an overview of the sequence of calls in a user's main program in this situation. Steps that are unchanged from the skeleton program presented in §5.1 are grayed out.

1. Initialize parallel or multi-threaded environment, if appropriate

- 2. Set problem dimensions etc.
- 3. Set vectors of initial values
- 4. Create CVODES object
- 5. Initialize CVODES
- 6. Specify integration tolerances
- 7. Set optional inputs
- 8. Create matrix object
- 9. Create linear solver object
- 10. Set linear solver optional inputs
- 11. Initialize sensitivity-independent quadrature problem
- 12. Define the sensitivity problem
- 13. Set sensitivity initial conditions
- 14. Activate sensitivity calculations
- 15. Set sensitivity analysis optional inputs

## 16. Set vector of initial values for quadrature variables

Typically, the quadrature variables should be initialized to 0.

## 17. Initialize sensitivity-dependent quadrature integration

Call CVodeQuadSensInit to specify the quadrature equation right-hand side function and to allocate internal memory related to quadrature integration. See §5.4.1 for details.

## 18. Set optional inputs for sensitivity-dependent quadrature integration

Call CVodeSetQuadSensErrCon to indicate whether or not quadrature variables should be used in the step size control mechanism. If so, one of the CVodeQuadSens\*tolerances functions must be called to specify the integration tolerances for quadrature variables. See §5.4.4 for details.

19. Advance solution in time

## 20. Extract sensitivity-dependent quadrature variables

Call CVodeGetQuadSens, CVodeGetQuadSens1, CVodeGetQuadSensDky or CVodeGetQuadSensDky1 to obtain the values of the quadrature variables or their derivatives at the current time. See  $\S5.4.3$  for details.

- 21. Get optional outputs
- 22. Extract sensitivity solution

#### 23. Get sensitivity-dependent quadrature optional outputs

Call CVodeGetQuadSens\* functions to obtain desired optional output related to the integration of sensitivity-dependent quadratures. See §5.4.5 for details.

- 24. Deallocate memory for solutions vector
- 25. Deallocate memory for sensitivity vectors

- 26. Deallocate memory for sensitivity-dependent quadrature variables
- 27. Free vector specification memory
- 28. Free linear solver and matrix memory
- 29. Free solver memory
- 30. Finalize MPI, if used

Note: CVodeQuadSensInit (step 17 above) can be called and quadrature-related optional inputs (step 18 above) can be set anywhere between steps 12 and 19.

## 5.4.1 Sensitivity-dependent quadrature initialization and deallocation

The function CVodeQuadSensInit activates integration of quadrature equations depending on sensitivities and allocates internal memory related to these calculations. If rhsQS is input as NULL, then CVODES uses an internal function that computes difference quotient approximations to the functions  $\bar{q}_i = q_y s_i + q_{p_i}$ , in the notation of (2.9). The form of the call to this function is as follows:

## CVodeQuadSensInit

Notes

Call flag = CVodeQuadSensInit(cvode\_mem, rhsQS, yQSO);

Description The function CVodeQuadSensInit provides required problem specifications, allocates internal memory, and initializes quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

rhsQS (CVQuadSensRhsFn) is the C function which computes  $f_{QS}$ , the right-hand side of the sensitivity-dependent quadrature equations (for full details see §5.4.6).

yQSO (N\_Vector \*) contains the initial values of sensitivity-dependent quadra-

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeQuadSensInit was successful.

 ${\tt CVODE\_MEM\_NULL} \ \ {\tt The\ CVODES\ memory\ was\ not\ initialized\ by\ a\ prior\ call\ to\ {\tt CVodeCreate}.$ 

CVODE\_MEM\_FAIL A memory allocation request failed.

CV\_NO\_SENS The sensitivities were not initialized by a prior call to CVodeSensInit or CVodeSensInit1.

CV\_ILL\_INPUT The parameter yQSO is NULL.

Before calling CVodeQuadSensInit, the user must enable the sensitivites by calling CVodeSensInit or CVodeSensInit1.

If an error occurred, CVodeQuadSensInit also sends an error message to the error handler function.

In terms of the number of quadrature variables  $N_q$  and maximum method order maxord, the size of the real workspace is increased as follows:

- Base value: lenrw = lenrw + (maxord+5) $N_q$
- If CVodeQuadSensSVtolerances is called: lenrw = lenrw  $+N_qN_s$

and the size of the integer workspace is increased as follows:

- Base value: leniw = leniw + (maxord+5) $N_q$
- ullet If CVodeQuadSensSVtolerances is called: leniw = leniw  $+N_qN_s$

The function CVodeQuadSensReInit, useful during the solution of a sequence of problems of same size, reinitializes quadrature-related internal memory and must follow a call to CVodeQuadSensInit. The number Nq of quadratures as well as the number Ns of sensitivities are assumed to be unchanged from the prior call to CVodeQuadSensInit. The call to the CVodeQuadSensReInit function has the form:

## CVodeQuadSensReInit

Call flag = CVodeQuadSensReInit(cvode\_mem, yQSO);

Description The function CVodeQuadSensReInit provides required problem specifications and reini-

tializes the sensitivity-dependent quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

yQSO (N\_Vector \*) contains the initial values of sensitivity-dependent quadra-

tures.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeQuadSensReInit was successful.

CVODE MEM\_NULL The CVODES memory was not initialized by a prior call to CVodeCreate.

CV\_NO\_SENS Memory space for the sensitivity calculation was not allocated by a

prior call to CVodeSensInit or CVodeSensInit1.

CV\_NO\_QUADSENS Memory space for the sensitivity quadratures integration was not al-

located by a prior call to CVodeQuadSensInit.

CV\_ILL\_INPUT The parameter yQSO is NULL.

Notes If an error occurred, CVodeQuadSensReInit also sends an error message to the error

handler function.

## CVodeQuadSensFree

Call CVodeQuadSensFree(cvode\_mem);

Description The function CVodeQuadSensFree frees the memory allocated for sensitivity quadrature

integration.

Arguments The argument is the pointer to the CVODES memory block (of type void \*).

Return value The function CVodeQuadSensFree has no return value.

Notes In general, CVodeQuadSensFree need not be called by the user, as it is invoked auto-

 ${\rm matically} \ {\rm by} \ {\tt CVodeFree}.$ 

## 5.4.2 CVODES solver function

Even if quadrature integration was enabled, the call to the main solver function CVode is exactly the same as in §4.5.5. However, in this case the return value flag can also be one of the following:

CV\_QSRHSFUNC\_ERR The sensitivity quadrature right-hand side function failed in an unrecover-

able manner.

CV\_FIRST\_QSRHSFUNC\_ERR The sensitivity quadrature right-hand side function failed at the first call.

quadrature 1.8.10 raine sand transfer and tr

CV\_REPTD\_QSRHSFUNC\_ERR Convergence test failures occurred too many times due to repeated recoverable errors in the quadrature right-hand side function. This flag will also be returned if the quadrature right-hand side function had repeated recoverable errors during the estimation of an initial step size (assuming the sensitivity quadrature variables are included in the error tests).

## 5.4.3 Sensitivity-dependent quadrature extraction functions

If sensitivity-dependent quadratures have been initialized by a call to CVodeQuadSensInit, or reinitialized by a call to CVodeQuadSensReInit, then CVODES computes a solution, sensitivity vectors, and quadratures depending on sensitivities at time t. However, CVode will still return only the solution y. Sensitivity-dependent quadratures can be obtained using one of the following functions:

## CVodeGetQuadSens

Call flag = CVodeGetQuadSens(cvode\_mem, &tret, yQS);

 ${\bf Description} \quad {\bf The \ function \ CVodeGetQuadSens \ returns \ the \ quadrature \ sensitivities \ solution \ vectors}$ 

after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

tret (realtype) the time reached by the solver (output).

yQS (N\_Vector \*) array of Ns computed sensitivity-dependent quadrature vec-

tors.

Return value The return value flag of CVodeGetQuadSens is one of:

CV\_SUCCESS CVodeGetQuadSens was successful.

 ${\tt CVODE\_MEM\_NULL}$  cvode\_mem was  ${\tt NULL}$ .

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_BAD\_DKY yQS or one of the yQS[i] is NULL.

The function CVodeGetQuadSensDky computes the k-th derivatives of the interpolating polynomials for the sensitivity-dependent quadrature variables at time t. This function is called by CVodeGetQuadSens with k = 0, but may also be called directly by the user.

## CVodeGetQuadSensDky

Call flag = CVodeGetQuadSensDky(cvode\_mem, t, k, dkyQS);

Description The function CVodeGetQuadSensDky returns derivatives of the quadrature sensitivities

solution vectors after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

 ${\tt t}$  (realtype) the time at which information is requested. The time  ${\tt t}$  must

fall within the interval defined by the last successful step taken by CVODES.

k (int) order of the requested derivative.

 $\tt dkyQS$  (N\_Vector \*) array of Ns the vector containing the derivatives on output.

This vector array must be allocated by the user.

Return value The return value flag of CVodeGetQuadSensDky is one of:

 ${\tt CV\_SUCCESS} \qquad {\tt CVodeGetQuadSensDky} \ {\tt succeeded}.$ 

CVODE\_MEM\_NULL The pointer to cvode\_mem was NULL.

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_BAD\_DKY dkyQS or one of the vectors dkyQS[i] is NULL.

 $\label{eq:cv_bad_k} \mbox{CV\_BAD\_K} \qquad \qquad \mbox{$k$ is not in the range $0,1,...,$ $\tt qlast}.$ 

CV\_BAD\_T The time t is not in the allowed range.

Quadrature sensitivity solution vectors can also be extracted separately for each parameter in turn through the functions CVodeGetQuadSens1 and CVodeGetQuadSensDky1, defined as follows:

## CVodeGetQuadSens1

Call flag = CVodeGetQuadSens1(cvode\_mem, &tret, is, yQS);

Description The function CVodeGetQuadSens1 returns the is-th sensitivity of quadratures after a

successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

tret (realtype) the time reached by the solver (output).

is (int) specifies which sensitivity vector is to be returned  $(0 \le is < N_s)$ .

yQS (N\_Vector) the computed sensitivity-dependent quadrature vector.

Return value The return value flag of CVodeGetQuadSens1 is one of:

 ${\tt CV\_SUCCESS} \qquad {\tt CVodeGetQuadSens1} \ {\rm was} \ {\rm successful}.$ 

CVODE\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_BAD\_IS The index is is not in the allowed range.

## CVodeGetQuadSensDky1

Call flag = CVodeGetQuadSensDky1(cvode\_mem, t, k, is, dkyQS);

 $\label{lem:decomposition} Description \quad \text{The function $\tt CVodeGetQuadSensDky1$ returns the $\tt k$-th derivative of the $\tt is$-th sensitivity}.$ 

solution vector after a successful return from CVode.

Arguments cvode\_mem (void \*) pointer to the memory previously allocated by CVodeInit.

t (realtype) specifies the time at which sensitivity information is requested.

The time t must fall within the interval defined by the last successful step

taken by CVODES.

k (int) order of derivative.

is (int) specifies the sensitivity derivative vector to be returned  $(0 \le is < N_s)$ .

dkyQS (N\_Vector) the vector containing the derivative on output. The space for

dkyQS must be allocated by the user.

Return value The return value flag of CVodeGetQuadSensDky1 is one of:

CV\_SUCCESS CVodeGetQuadDky1 succeeded.

CVODE\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_SENS Forward sensitivity analysis was not initialized.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_BAD\_DKY dkyQS is NULL.

CV\_BAD\_IS The index is is not in the allowed range.

CV\_BAD\_K k is not in the range 0, 1, ..., qlast.

CV\_BAD\_T The time t is not in the allowed range.

## 5.4.4 Optional inputs for sensitivity-dependent quadrature integration

CVODES provides the following optional input functions to control the integration of sensitivity-dependent quadrature equations.

## CVodeSetQuadSensErrCon

Call flag = CVodeSetQuadSensErrCon(cvode\_mem, errconQS)

Description The function CVodeSetQuadSensErrCon specifies whether or not the quadrature vari-

ables are to be used in the step size control mechanism. If they are, the user must call one of the functions CVodeQuadSensSStolerances, CVodeQuadSensSVtolerances, or CVodeQuadSensEEtolerances to specify the integration tolerances for the quadrature

variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

errconQS (booleantype) specifies whether sensitivity quadrature variables are to be included (SUNTRUE) or not (SUNFALSE) in the error control mechanism.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CVODE\_MEM\_NULL cvode\_mem is NULL.

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

Notes By default, errconQS is set to SUNFALSE.

It is illegal to call CVodeSetQuadSensErrCon before a call to CVodeQuadSensInit.

If the quadrature variables are part of the step size control mechanism, one of the following functions must be called to specify the integration tolerances for quadrature variables.

## CVodeQuadSensSStolerances

Call flag = CVodeQuadSensSVtolerances(cvode\_mem, reltolQS, abstolQS);

Description The function CVodeQuadSensSStolerances specifies scalar relative and absolute toler-

ances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

reltolQS (realtype) is the scalar relative error tolerance.

 $\verb"abstolQS" (realtype*)" is a pointer to an array containing the <math>\verb"Ns"$  scalar absolute error

tolerances.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_ILL\_INPUT One of the input tolerances was negative.

## ${\tt CVodeQuadSensSVtolerances}$

Call flag = CVodeQuadSensSVtolerances(cvode\_mem, reltolQS, abstolQS);

Description The function CVodeQuadSensSVtolerances specifies scalar relative and vector absolute

tolerances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

reltolQS (realtype) is the scalar relative error tolerance.

abstolQS (N\_Vector\*) is an array of Ns variables of type N\_Vector. The N\_Vector abstolS[is] specifies the vector tolerances for is-th quadrature sensitivity.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CV\_NO\_QUAD Quadrature integration was not initialized.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

CV\_ILL\_INPUT One of the input tolerances was negative.

#### CVodeQuadSensEEtolerances

Call flag = CVodeQuadSensEEtolerances(cvode\_mem);

Description A call to the function CVodeQuadSensEEtolerances specifies that the tolerances for the

sensitivity-dependent quadratures should be estimated from those provided for the pure

quadrature variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional value has been successfully set.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_SENS Sensitivities were not activated.

CV\_NO\_QUADSENS Quadratures depending on the sensitivities were not activated.

Notes When CVodeQuadSensEEtolerances is used, before calling CVode, integration of pure

quadratures must be initialized (see 4.7.1) and tolerances for pure quadratures must be

also specified (see 4.7.4).

## 5.4.5 Optional outputs for sensitivity-dependent quadrature integration

CVODES provides the following functions that can be used to obtain solver performance information related to quadrature integration.

## CVodeGetQuadSensNumRhsEvals

Call flag = CVodeGetQuadSensNumRhsEvals(cvode\_mem, &nrhsQSevals);

Description The function CVodeGetQuadSensNumRhsEvals returns the number of calls made to the

user's quadrature right-hand side function.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nrhsQSevals (long int) number of calls made to the user's rhsQS function.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

CV\_NO\_QUADSENS Sensitivity-dependent quadrature integration has not been initialized.

## CVodeGetQuadSensNumErrTestFails

Call flag = CVodeGetQuadSensNumErrTestFails(cvode\_mem, &nQSetfails);

Description The function CVodeGetQuadSensNumErrTestFails returns the number of local error

test failures due to quadrature variables.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nQSetfails (long int) number of error test failures due to quadrature variables.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

 ${\tt CV\_NO\_QUADSENS} \ \ {\tt Sensitivity-dependent} \ \ {\tt quadrature} \ \ {\tt integration} \ \ {\tt has} \ \ {\tt not} \ \ {\tt been} \ \ {\tt initialized}.$ 

## ${\tt CVodeGetQuadSensErrWeights}$

Call flag = CVodeGetQuadSensErrWeights(cvode\_mem, eQSweight);

 $\label{prop:local_prop_local} Description \quad The \ function \ {\tt CVodeGetQuadSensErrWeights} \ \ {\tt returns} \ \ the \ quadrature \ {\tt error} \ \ {\tt weights} \ \ {\tt at}$ 

the current time.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

eQSweight (N\_Vector \*) array of quadrature error weight vectors at the current time.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The optional output value has been successfully set.

CVODE\_MEM\_NULL The cvode\_mem pointer is NULL.

 ${\tt CV\_NO\_QUADSENS} \ \ {\tt Sensitivity-dependent} \ \ {\tt quadrature} \ \ {\tt integration} \ \ {\tt has} \ \ {\tt not} \ \ {\tt been} \ \ {\tt initialized}.$ 

Notes The user must allocate memory for eQSweight.

If quadratures were not included in the error control mechanism (through a call to CVodeSetQuadSensErrCon with errconQS = SUNTRUE), then this function does not set

the eQSweight array.

## ${\tt CVodeGetQuadSensStats}$

Call flag = CVodeGetQuadSensStats(cvode\_mem, &nrhsQSevals, &nQSetfails);

 $\label{thm:condecomp} \textbf{Description} \quad \textbf{The function $\tt CVodeGetQuadSensStats} \ \ \textbf{returns the CVODES integrator statistics as a} \\$ 

group.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

nrhsQSevals (long int) number of calls to the user's rhsQS function.

nQSetfails (long int) number of error test failures due to quadrature variables.

Return value The return value flag (of type int) is one of

CV\_SUCCESS the optional output values have been successfully set.

CVODE\_MEM\_NULL the cvode\_mem pointer is NULL.

CV\_NO\_QUADSENS Sensitivity-dependent quadrature integration has not been initialized.

# 5.4.6 User-supplied function for sensitivity-dependent quadrature integration

For the integration of sensitivity-dependent quadrature equations, the user must provide a function that defines the right-hand side of those quadrature equations. For the sensitivities of quadratures (2.9) with integrand q, the appropriate right-hand side functions are given by:  $\bar{q}_i = q_y s_i + q_{p_i}$ . This user function must be of type CVQuadSensRhsFn defined as follows:

#### CVQuadSensRhsFn

Definition typedef int (\*CVQuadSensRhsFn)(int Ns, realtype t, N\_Vector y,

N\_Vector yS, N\_Vector yQdot,

N\_Vector \*rhsvalQS, void \*user\_data,

N\_Vector tmp1, N\_Vector tmp2)

Purpose This function computes the sensitivity quadrature equation right-hand side for a given

value of the independent variable t and state vector y.

Arguments Ns is the number of sensitivity vectors.

t is the current value of the independent variable.

y is the current value of the dependent variable vector, y(t).

yS is an array of Ns variables of type N\_Vector containing the dependent sen-

sitivity vectors  $s_i$ .

yQdot is the current value of the quadrature right-hand side, q.

rhsvalQS array of Ns vectors to contain the right-hand sides.

 ${\tt user\_data} \ \ {\rm is} \ \ {\rm the} \ \ {\tt user\_data} \ \ {\rm pointer} \ \ {\rm passed} \ \ {\tt to} \ \ {\tt CVodeSetUserData}.$ 

tmp1

tmp2 are N\_Vectors which can be used as temporary storage.

Return value A CVQuadSensRhsFn should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CV\_QRHS\_FAIL is returned).

Notes Allocation of memory for rhsvalQS is automatically handled within CVODES.

Here y is of type N\_Vector and yS is a pointer to an array containing Ns vectors of type N\_Vector. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with respect to their N\_Vector arguments (see §7.1 and §7.2).

There are two situations in which recovery is not possible even if CVQuadSensRhsFn function returns a recoverable error flag. One is when this occurs at the very first call to the CVQuadSensRhsFn (in which case CVODES returns CV\_FIRST\_QSRHSFUNC\_ERR). The other is when a recoverable error is reported by CVQuadSensRhsFn after an error test failure, while the linear multistep method order is equal to 1 (in which case CVODES returns CV\_UNREC\_QSRHSFUNC\_ERR).

# 5.5 Note on using partial error control

For some problems, when sensitivities are excluded from the error control test, the behavior of CVODES may appear at first glance to be erroneous. One would expect that, in such cases, the sensitivity variables would not influence in any way the step size selection. A comparison of the solver diagnostics reported for cvsdenx and the second run of the cvsfwddenx example in [35] indicates that this may not always be the case.

The short explanation of this behavior is that the step size selection implemented by the error control mechanism in CVODES is based on the magnitude of the correction calculated by the nonlinear solver. As mentioned in §5.2.1, even with partial error control selected (in the call to CVodeSetSensErrCon), the sensitivity variables are included in the convergence tests of the nonlinear solver

When using the simultaneous corrector method (§2.6), the nonlinear system that is solved at each step involves both the state and sensitivity equations. In this case, it is easy to see how the sensitivity variables may affect the convergence rate of the nonlinear solver and therefore the step size selection. The case of the staggered corrector approach is more subtle. After all, in this case (ism = CV\_STAGGERED or CV\_STAGGERED1 in the call to CVodeSensInit/CVodeSensInit1), the sensitivity variables at a given step are computed only once the solver for the nonlinear state equations has converged. However, if the nonlinear system corresponding to the sensitivity equations has convergence problems, CVODES will attempt to improve the initial guess by reducing the step size in order to provide a better prediction of the sensitivity variables. Moreover, even if there are no convergence failures in the solution of the sensitivity system, CVODES may trigger a call to the linear solver's setup routine which typically involves reevaluation of Jacobian information (Jacobian approximation in the case of CVDENSE and CVBAND, or preconditioner data in the case of the Krylov solvers). The new Jacobian information will be used by subsequent calls to the nonlinear solver for the state equations and, in this way, potentially affect the step size selection.

When using the simultaneous corrector method it is not possible to decide whether nonlinear solver convergence failures or calls to the linear solver setup routine have been triggered by convergence problems due to the state or the sensitivity equations. When using one of the staggered corrector methods however, these situations can be identified by carefully monitoring the diagnostic information

provided through optional outputs. If there are no convergence failures in the sensitivity nonlinear solver, and none of the calls to the linear solver setup routine were made by the sensitivity nonlinear solver, then the step size selection is not affected by the sensitivity variables.

Finally, the user must be warned that the effect of appending sensitivity equations to a given system of ODEs on the step size selection (through the mechanisms described above) is problem-dependent and can therefore lead to either an increase or decrease of the total number of steps that CVODES takes to complete the simulation. At first glance, one would expect that the impact of the sensitivity variables, if any, would be in the direction of increasing the step size and therefore reducing the total number of steps. The argument for this is that the presence of the sensitivity variables in the convergence test of the nonlinear solver can only lead to additional iterations (and therefore a smaller final iteration error), or to additional calls to the linear solver setup routine (and therefore more up-to-date Jacobian information), both of which will lead to larger steps being taken by CVODES. However, this is true only locally. Overall, a larger integration step taken at a given time may lead to step size reductions at later times, due to either nonlinear solver convergence failures or error test failures.

# Chapter 6

# Using CVODES for Adjoint Sensitivity Analysis

This chapter describes the use of CVODES to compute sensitivities of derived functions using adjoint sensitivity analysis. As mentioned before, the adjoint sensitivity module of CVODES provides the infrastructure for integrating backward in time any system of ODEs that depends on the solution of the original IVP, by providing various interfaces to the main CVODES integrator, as well as several supporting user-callable functions. For this reason, in the following sections we refer to the backward problem and not to the adjoint problem when discussing details relevant to the ODEs that are integrated backward in time. The backward problem can be the adjoint problem (2.19) or (2.22), and can be augmented with some quadrature differential equations.

CVODES uses various constants for both input and output. These are defined as needed in this chapter, but for convenience are also listed separately in Appendix B.

We begin with a brief overview, in the form of a skeleton user program. Following that are detailed descriptions of the interface to the various user-callable functions and of the user-supplied functions that were not already described in Chapter 4.

# 6.1 A skeleton of the user's main program

The following is a skeleton of the user's main program as an application of CVODES. The user program is to have these steps in the order indicated, unless otherwise noted. For the sake of brevity, we defer many of the details to the later sections. As in §4.4, most steps are independent of the NVECTOR implementation used; where this is not the case, refer to Chapter 7 for specifics. Steps that are unchanged from the skeleton programs presented in §4.4, §5.1, and §5.4, are grayed out.

1. Include necessary header files

The cvodes.h header file also defines additional types, constants, and function prototypes for the adjoint sensitivity module user-callable functions. In addition, the main program should include an NVECTOR implementation header file (for the particular implementation used), and, if Newton iteration was selected, the main header file of the desired linear solver module.

2. Initialize parallel or multi-threaded environment, if appropriate

#### Forward problem

- 3. Set problem dimensions etc. for the forward problem
- 4. Set initial conditions for the forward problem
- 5. Create CVODES object for the forward problem

- 6. Initial CVODES for the forward problem
- 7. Specify integration tolerances for forward problem
- 8. Set optional inputs for the forward problem
- 9. Create matrix object for the forward problem
- 10. Create linear solver object for the forward problem
- 11. Set linear solver optional inputs for the forward problem
- 12. Attach linear solver module for the forward problem
- 13. Initialize quadrature problem or problems for forward problems, using CVodeQuadInit and/or CVodeQuadSensInit.
- 14. Initialize forward sensitivity problem
- 15. Specify rootfinding

## 16. Allocate space for the adjoint computation

Call CVodeAdjInit() to allocate memory for the combined forward-backward problem (see §6.2.1 for details). This call requires Nd, the number of steps between two consecutive checkpoints. CVodeAdjInit also specifies the type of interpolation used (see §2.7.1).

## 17. Integrate forward problem

Call CVodeF, a wrapper for the CVODES main integration function CVode, either in CV\_NORMAL mode to the time tout or in CV\_ONE\_STEP mode inside a loop (if intermediate solutions of the forward problem are desired (see  $\S6.2.2$ )). The final value of tret is then the maximum allowable value for the endpoint T of the backward problem.

## Backward problem(s)

## 18. Set problem dimensions etc. for the backward problem

This generally includes the backward problem vector length NB, and possibly the local vector length NBlocal.

## 19. Set initial values for the backward problem

Set the endpoint time tBO = T, and set the corresponding vector yBO at which the backward problem starts.

## 20. Create the backward problem

Call CVodeCreateB, a wrapper for CVodeCreate, to create the CVODES memory block for the new backward problem. Unlike CVodeCreate, the function CVodeCreateB does not return a pointer to the newly created memory block (see §6.2.3). Instead, this pointer is attached to the internal adjoint memory block (created by CVodeAdjInit) and returns an identifier called which that the user must later specify in any actions on the newly created backward problem.

## 21. Allocate memory for the backward problem

Call CVodeInitB (or CVodeInitBS, when the backward problem depends on the forward sensitivities). The two functions are actually wrappers for CVodeInit and allocate internal memory, specify problem data, and initialize CVODES at tBO for the backward problem (see §6.2.3).

## 22. Specify integration tolerances for backward problem

Call CVodeSStolerancesB(...) or CVodeSVtolerancesB(...) to specify a scalar relative tolerance and scalar absolute tolerance or scalar relative tolerance and a vector of absolute tolerances, respectively. The functions are wrappers for CVodeSStolerances and CVodeSVtolerances, but they require an extra argument which, the identifier of the backward problem returned by CVodeCreateB. See §6.2.4 for more information.

## 23. Set optional inputs for the backward problem

Call CVodeSet\*B functions to change from their default values any optional inputs that control the behavior of CVODES. Unlike their counterparts for the forward problem, these functions take an extra argument which, the identifier of the backward problem returned by CVodeCreateB (see §6.2.8).

## 24. Create matrix object for the backward problem

If a direct linear solver is to be used within a Newton iteration then a template Jacobian matrix must be created by using the appropriate functions defined by the particular SUNMATRIX implementation.

NOTE: The dense, banded, and sparse matrix objects are usable only in a serial or threaded environment.

Note also that it is not required to use the same matrix type for both the forward and the backward problems.

#### 25. Create linear solver object for the backward problem

Create the linear solver object for the backward problem by using the appropriate functions defined by the particular SUNLINSOL implementation desired.

Note that it is not required to use the same linear solver module for both the forward and the backward problems; for example, the forward problem could be solved with the CVDLS linear solver module and the backward problem with CVSPILS linear solver module.

#### 26. Set linear solver interface optional inputs for the backward problem

Call CVDlsSet\*B or CVSpilsSet\*B functions to change optional inputs specific to that linear solver interface. See §6.2.8 for details.

#### 27. Initialize quadrature calculation

If additional quadrature equations must be evaluated, call CVodeQuadInitB or CVodeQuadInitBS (if quadrature depends also on the forward sensitivities) as shown in §6.2.10.1. These functions are wrappers around CVodeQuadInit and can be used to initialize and allocate memory for quadrature integration. Optionally, call CVodeSetQuad\*B functions to change from their default values optional inputs that control the integration of quadratures during the backward phase.

## 28. Integrate backward problem

Call CVodeB, a second wrapper around the CVODES main integration function CVode, to integrate the backward problem from tBO (see  $\S6.2.6$ ). This function can be called either in CV\_NORMAL or CV\_ONE\_STEP mode. Typically, CVodeB will be called in CV\_NORMAL mode with an end time equal to the initial time  $t_0$  of the forward problem.

## 29. Extract quadrature variables

If applicable, call CVodeGetQuadB, a wrapper around CVodeGetQuad, to extract the values of the quadrature variables at the time returned by the last call to CVodeB. See §6.2.10.2.

#### 30. Deallocate memory

Upon completion of the backward integration, call all necessary deallocation functions. These include appropriate destructors for the vectors y and yB, a call to CVodeFree to free the CVODES

memory block for the forward problem. If one or more additional Adjoint Sensitivity Analyses are to be done for this problem, a call to CVodeAdjFree (see §6.2.1) may be made to free and deallocate memory allocated for the backward problems, followed by a call to CVodeAdjInit.

## 31. Free linear solver and matrix memory for the backward problem

## 32. Finalize MPI, if used

The above user interface to the adjoint sensitivity module in CVODES was motivated by the desire to keep it as close as possible in look and feel to the one for ODE IVP integration. Note that if steps (18)-(29) are not present, a program with the above structure will have the same functionality as one described in §4.4 for integration of ODEs, albeit with some overhead due to the checkpointing scheme.

If there are multiple backward problems associated with the same forward problem, repeat steps (18)-(29) above for each successive backward problem. In the process, each call to CVodeCreateB creates a new value of the identifier which.

#### 6.2 User-callable functions for adjoint sensitivity analysis

#### 6.2.1Adjoint sensitivity allocation and deallocation functions

After the setup phase for the forward problem, but before the call to CVodeF, memory for the combined forward-backward problem must be allocated by a call to the function CVodeAdjInit. The form of the call to this function is

## CVodeAdjInit

Call flag = CVodeAdjInit(cvode\_mem, Nd, interpType);

Description The function CVodeAdjInit updates CVODES memory block by allocating the internal

memory needed for backward integration. Space is allocated for the  $Nd = N_d$  interpo-

lation data points, and a linked list of checkpoints is initialized.

Arguments (void \*) is the pointer to the CVODES memory block returned by a previcvode\_mem ous call to CVodeCreate.

> Nd (long int) is the number of integration steps between two consecutive

checkpoints.

interpType (int) specifies the type of interpolation used and can be CV\_POLYNOMIAL or CV\_HERMITE, indicating variable-degree polynomial and cubic Hermite

interpolation, respectively (see  $\S 2.7.1$ ).

Return value The return value flag (of type int) is one of:

CV\_SUCCESS CVodeAdjInit was successful.

A memory allocation request has failed. CV\_MEM\_FAIL

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_ILL\_INPUT One of the parameters was invalid: Nd was not positive or interpType

is not one of the CV\_POLYNOMIAL or CV\_HERMITE.

The user must set Nd so that all data needed for interpolation of the forward problem solution between two checkpoints fits in memory. CVodeAdjInit attempts to allocate space for (2Nd+3) variables of type N\_Vector.

If an error occurred, CVodeAdjInit also sends a message to the error handler function.

## CVodeAdjReInit

Notes

Call flag = CVodeAdjReInit(cvode\_mem); Description The function CVodeAdjReInit reinitializes the CVODES memory block for ASA, assum-

ing that the number of steps between check points and the type of interpolation remain

unchanged.

Arguments cvode\_mem (void \*) is the pointer to the CVODES memory block returned by a previous

call to CVodeCreate.

Return value The return value flag (of type int) is one of:

 ${\tt CV\_SUCCESS} \quad {\tt CVodeAdjReInit} \ {\tt was} \ {\tt successful}.$ 

 ${\tt CV\_MEM\_NULL}$  cvode\_mem was  ${\tt NULL}$ .

CV\_NO\_ADJ The function CVodeAdjInit was not previously called.

Notes The list of check points (and associated memory) is deleted.

The list of backward problems is kept. However, new backward problems can be added to this list by calling CVodeCreateB. If a new list of backward problems is also needed, then free the adjoint memory (by calling CVodeAdjFree) and reinitialize ASA with CVodeAdjInit.

The CVODES memory for the forward and backward problems can be reinitialized separately by calling CVodeReInit and CVodeReInitB, respectively.

## CVodeAdjFree

Call CVodeAdjFree(cvode\_mem);

 $\label{preconstraint} \textbf{Description} \quad \text{The function $\tt CVodeAdjFree} \ \text{frees the memory related to backward integration allocated}$ 

by a previous call to CVodeAdjInit.

Arguments The only argument is the CVODES memory block pointer returned by a previous call to

CVodeCreate.

Return value The function CVodeAdjFree has no return value.

Notes This function frees all memory allocated by CVodeAdjInit. This includes workspace

memory, the linked list of checkpoints, memory for the interpolation data, as well as the CVODES memory for the backward integration phase. Unless one or more further calls to CVodeAdjInit are to be made, CVodeAdjFree should not be called by the user,

as it is invoked automatically by CVodeFree.

## 6.2.2 Forward integration function

The function CVodeF is very similar to the CVODES function CVode (see §4.5.5) in that it integrates the solution of the forward problem and returns the solution in y. At the same time, however, CVodeF stores checkpoint data every Nd integration steps. CVodeF can be called repeatedly by the user. Note that CVodeF is used only for the forward integration pass within an Adjoint Sensitivity Analysis. It is not for use in Forward Sensitivity Analysis; for that, see Chapter 5. The call to this function has the form

## CVodeF

Call flag = CVodeF(cvode\_mem, tout, yret, &tret, itask, &ncheck);

Description The function CVodeF integrates the forward problem over an interval in t and saves

checkpointing data.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

tout (realtype) the next time at which a computed solution is desired.

yret  $(N_{\text{-}}\text{Vector})$  the computed solution vector y.

tret (realtype) the time reached by the solver (output).

itask (int) a flag indicating the job of the solver for the next step. The CV\_NORMAL

task is to have the solver take internal steps until it has reached or just passed the user-specified tout parameter. The solver then interpolates in order to return an approximate value of y(tout). The CV\_ONE\_STEP option tells the solver to just take one internal step and return the solution at the point

reached by that step.

ncheck (int) the number of (internal) checkpoints stored so far.

Return value On return, CVodeF returns the vector yret and a corresponding independent variable value t = tret, such that yret is the computed value of y(t). Additionally, it returns in ncheck the number of internal checkpoints saved; the total number of checkpoint intervals is ncheck+1. The return value flag (of type int) will be one of the following.

For more details see  $\S4.5.5$ .

CV\_SUCCESS CVodeF succeeded.

CV\_TSTOP\_RETURN CVodeF succeeded by reaching the optional stopping point.

CV\_ROOT\_RETURN CVodeF succeeded and found one or more roots. In this case, tret

is the location of the root. If nrtfn > 1, call CVodeGetRootInfo to

see which  $g_i$  were found to have a root.

CV\_NO\_MALLOC The function CVodeInit has not been previously called.

CV\_ILL\_INPUT One of the inputs to CVodeF is illegal.

 ${\tt CV\_TOO\_MUCH\_WORK}$  The solver took mxstep internal steps but could not reach tout.

 $CV\_TOO\_MUCH\_ACC$  The solver could not satisfy the accuracy demanded by the user for

some internal step.

CV\_ERR\_FAILURE Error test failures occurred too many times during one internal time

step or occurred with  $|h| = h_{min}$ .

CV\_CONV\_FAILURE Convergence test failures occurred too many times during one inter-

nal time step or occurred with  $|h| = h_{min}$ .

 ${\tt CV\_LSETUP\_FAIL} \qquad {\tt The \ linear \ solver's \ setup \ function \ failed \ in \ an \ unrecoverable \ manner}.$ 

 ${\tt CV\_LSOLVE\_FAIL} \qquad {\tt The \ linear \ solver's \ solve \ function \ failed \ in \ an \ unrecoverable \ manner.}$ 

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_MEM\_FAIL A memory allocation request has failed (in an attempt to allocate

space for a new checkpoint).

Notes All failure return values are negative and therefore a test flag< 0 will trap all CVodeF failures.

At this time, CVodeF stores checkpoint information in memory only. Future versions will provide for a safeguard option of dumping checkpoint data into a temporary file as needed. The data stored at each checkpoint is basically a snapshot of the CVODES internal memory block and contains enough information to restart the integration from that time and to proceed with the same step size and method order sequence as during the forward integration.

In addition, CVodeF also stores interpolation data between consecutive checkpoints so that, at the end of this first forward integration phase, interpolation information is already available from the last checkpoint forward. In particular, if no checkpoints were necessary, there is no need for the second forward integration phase.

It is illegal to change the integration tolerances between consecutive calls to CVodeF, as this information is not captured in the checkpoint data.

## 6.2.3 Backward problem initialization functions

The functions CVodeCreateB and CVodeInitB (or CVodeInitBS) must be called in the order listed. They instantiate a CVODES solver object, provide problem and solution specifications, and allocate internal memory for the backward problem.

## CVodeCreateB

Call flag = CVodeCreateB(cvode\_mem, lmmB, iterB, &which);

Description The function CVodeCreateB instantiates a CVODES solver object and specifies the solu-

tion method for the backward problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

lmmB (int) specifies the linear multistep method and may be one of two possible

values: CV\_ADAMS or CV\_BDF.

iterB (int) specifies the type of nonlinear solver iteration and may be either

CV\_NEWTON or CV\_FUNCTIONAL.

which (int) contains the identifier assigned by CVODES for the newly created back-

ward problem. Any call to CVode\*B functions requires such an identifier.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The call to CVodeCreateB was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_MEM\_FAIL A memory allocation request has failed.

There are two initialization functions for the backward problem – one for the case when the backward problem does not depend on the forward sensitivities, and one for the case when it does. These two functions are described next.

The function CVodeInitB initializes the backward problem when it does not depend on the forward sensitivities. It is essentially a wrapper for CVodeInit with some particularization for backward integration, as described below.

## CVodeInitB

Call flag = CVodeInitB(cvode\_mem, which, rhsB, tB0, yB0);

Description The function CVodeInitB provides problem specification, allocates internal memory,

and initializes the backward problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

which (int) represents the identifier of the backward problem.

rhsB (CVRhsFnB) is the C function which computes fB, the right-hand side of the backward ODE problem. This function has the form rhsB(t, y, yB,

yBdot, user\_dataB) (for full details see §6.3.1).

tBO (realtype) specifies the endpoint T where final conditions are provided for the backward problem, normally equal to the endpoint of the forward integration.

yBO (N\_Vector) is the initial value (at t = tBO) of the backward solution.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeInitB was successful.

CV\_NO\_MALLOC The function CVodeInit has not been previously called.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_BAD\_TB0 The final time tB0 was outside the interval over which the forward problem was solved.

CV\_ILL\_INPUT The parameter which represented an invalid identifier, or either yBO or rhsB was NULL.

Notes The memory allocated by CVodeInitB is deallocated by the function CVodeAdjFree.

For the case when backward problem also depends on the forward sensitivities, user must call CVodeInitBS instead of CVodeInitB. Only the third argument of each function differs between these two functions.

## CVodeInitBS

Call flag = CVodeInitBS(cvode\_mem, which, rhsBS, tB0, yB0);

Description The function CVodeInitBS provides problem specification, allocates internal memory, and initializes the backward problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

which (int) represents the identifier of the backward problem.

rhsBS (CVRhsFnBS) is the C function which computes fB, the right-hand side of the backward ODE problem. This function has the form rhsBS(t, y, yS, yB, yBdot, user\_dataB) (for full details see §6.3.2).

tB0 (realtype) specifies the endpoint T where final conditions are provided for the backward problem.

yB0 (N\_Vector) is the initial value (at t = tB0) of the backward solution.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeInitB was successful.

CV\_NO\_MALLOC The function CVodeInit has not been previously called.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_BAD\_TB0 The final time tB0 was outside the interval over which the forward problem was solved.

CV\_ILL\_INPUT The parameter which represented an invalid identifier, either yBO or rhsBS was NULL, or sensitivities were not active during the forward integration.

Notes The memory allocated by CVodeInitBS is deallocated by the function CVodeAdjFree.

The function CVodeReInitB reinitializes CVODES for the solution of a series of backward problems, each identified by a value of the parameter which. CVodeReInitB is essentially a wrapper for CVodeReInit, and so all details given for CVodeReInit in §4.5.9 apply here. Also note that CVodeReInitB can be called to reinitialize the backward problem even it has been initialized with the sensitivity-dependent version CVodeInitBS. Before calling CVodeReInitB for a new backward problem, call any desired solution extraction functions CVodeGet\*\* associated with the previous backward problem. The call to the CVodeReInitB function has the form

#### CVodeReInitB

Call flag = CVodeReInitB(cvode\_mem, which, tB0, yB0)

Description The function CVodeReInitB reinitializes a CVODES backward problem.

Arguments cvode\_mem (void \*) pointer to CVODES memory block returned by CVodeCreate.

which (int) represents the identifier of the backward problem.

 $\verb|tb0| \qquad \qquad (\verb|realtype|) \text{ specifies the endpoint } T \text{ where final conditions are provided for}$ 

the backward problem.

yB0 (N\_Vector) is the initial value (at t = tB0) of the backward solution.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeReInitB was successful.

CV\_NO\_MALLOC The function CVodeInit has not been previously called.

CV\_MEM\_NULL The cvode\_mem memory block pointer was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_BAD\_TB0 The final time tB0 is outside the interval over which the forward problem was solved.

CV\_ILL\_INPUT The parameter which represented an invalid identifier, or yBO was NULL.

## 6.2.4 Tolerance specification functions for backward problem

One of the following two functions must be called to specify the integration tolerances for the backward problem. Note that this call must be made after the call to CVodeInitB or CVodeInitBS.

## CVodeSStolerancesB

Call flag = CVodeSStolerancesB(cvode\_mem, which, reltolB, abstolB);

Description The function CVodeSStolerancesB specifies scalar relative and absolute tolerances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

which (int) represents the identifier of the backward problem.

reltolB (realtype) is the scalar relative error tolerance.

abstolB (realtype) is the scalar absolute error tolerance.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSStolerancesB was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call to CVodeCreate.

CV\_NO\_MALLOC The allocation function CVodeInit has not been called.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_ILL\_INPUT One of the input tolerances was negative.

#### CVodeSVtolerancesB

Call flag = CVodeSVtolerancesB(cvode\_mem, which, reltolB, abstolB);

 $\label{prop:condense} Description \quad The function {\tt CVodeSVtolerancesB} \ specifies \ scalar \ relative \ tolerance \ and \ vector \ absolute$ 

tolerances.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

which (int) represents the identifier of the backward problem.

reltol (realtype) is the scalar relative error tolerance.

abstol (N\_Vector) is the vector of absolute error tolerances.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeSVtolerancesB was successful.

CV\_MEM\_NULL The CVODES memory block was not initialized through a previous call

to CVodeCreate.

CV\_NO\_MALLOC The allocation function CVodeInit has not been called.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_ILL\_INPUT The relative error tolerance was negative or the absolute tolerance had

a negative component.

Notes This choice of tolerances is important when the absolute error tolerance needs to be

different for each component of the state vector y.

## 6.2.5 Linear solver initialization functions for backward problem

All CVODES linear solver modules available for forward problems are available for the backward problem. They should be created as for the forward problem then attached to the memory structure for the backward problem using one of the following functions.

## CVDlsSetLinearSolverB

Call flag = CVDlsSetLinearSolverB(cvode\_mem, which, LS, A);

Description

The function CVDlsSetLinearSolverB attaches a direct SUNLINSOL object LS and corresponding template Jacobian SUNMATRIX object A to CVODES, initializing the CVDLS direct linear solver interface for solution of the backward problem.

The user's main program must include the cvodes\_direct.h header file.

Arguments

cvode\_mem (void \*) pointer to the IDAS memory block.

which (int) represents the identifier of the backward problem returned by CVodeCreateB.

LS (SUNLinearSolver) SUNLINSOL object to use for solving Newton linear sys-

tems for the backward problem.

A (SUNMatrix) SUNMATRIX object for used as a template for the Jacobian for the backward problem (must have a type compatible with the linear solver

object).

Return value The return value flag (of type int) is one of

CVDLS\_SUCCESS The CVDLS initialization was successful.

CVDLS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVDLS\_ILL\_INPUT The CVDLS solver is not compatible with the current NVECTOR module.

CVDLS\_MEM\_FAIL A memory allocation request failed.

CVDLS\_NO\_ADJ The function CVAdjInit has not been previously called.

CVDLS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes

The CVDLS linear solver is not compatible with all implementations of the SUNLINSOL and NVECTOR modules. Specifically, CVDLS requires use of a *direct* SUNLINSOL object and a serial or theaded NVECTOR module. Additional compatibility limitations for each SUNLINSOL object (i.e. SUNMATRIX and NVECTOR object compatibility) are described in Chapter 9.

#### CVSpilsSetLinearSolverB

Call flag = CVSpilsSetLinearSolverB(ida.mem, which, LS);

Description

The function CVSpilsSetLinearSolver attaches an iterative SUNLINSOL object LS to CVODES, initializing the CVSPILS scaled, preconditioned, iterative linear solver interface to use for the backward problem.

The user's main program must include the cvs\_spils.h header file.

Arguments

cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) represents the identifier of the backward problem returned by CVodeCreateB.

LS (SUNLinearSolver) SUNLINSOL object to use for solving Newton linear sys-

tems for the backward problem.

Return value The return value flag (of type int) is one of

CVSPILS\_SUCCESS The CVSPILS initialization was successful.

CVSPILS\_MEM\_NULL The cvode\_mem pointer is NULL.

CVSPILS\_ILL\_INPUT The CVSPILS solver is not compatible with the current NVECTOR module.

CVSPILS\_MEM\_FAIL A memory allocation request failed.

CVSPILS\_NO\_ADJ The function CVAdjInit has not been previously called.

CVSPILS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes

The CVSPILS linear solver interface is not compatible with all implementations of the SUNLINSOL and NVECTOR modules. Specifically, CVSPILS requires use of an *iterative* SUNLINSOL object. Additional compatibility limitations for each SUNLINSOL object (i.e. required NVECTOR routines) are described in Chapter 9.

## 6.2.6 Backward integration function

The function CVodeB performs the integration of the backward problem. It is essentially a wrapper for the CVODES main integration function CVode and, in the case in which checkpoints were needed, it evolves the solution of the backward problem through a sequence of forward-backward integration pairs between consecutive checkpoints. The first run of each pair integrates the original IVP forward in time and stores interpolation data; the second run integrates the backward problem backward in time and performs the required interpolation to provide the solution of the IVP to the backward problem.

The function CVodeB does not return the solution yB itself. To obtain that, call the function CVodeGetB, which is also described below.

The CVodeB function does not support rootfinding, unlike CVodeF, which supports the finding of roots of functions of (t, y). If rootfinding was performed by CVodeF, then for the sake of efficiency, it should be disabled for CVodeB by first calling CVodeRootInit with nrtfn = 0.

The call to CVodeB has the form

CVodeB

Call flag = CVodeB(cvode\_mem, tBout, itaskB);

Description The function CVodeB integrates the backward ODE problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory returned by CVodeCreate.

tBout (realtype) the next time at which a computed solution is desired.

itaskB (int) a flag indicating the job of the solver for the next step. The CV\_NORMAL

task is to have the solver take internal steps until it has reached or just passed the user-specified value tBout. The solver then interpolates in order to return an approximate value of yB(tBout). The CV\_ONE\_STEP option tells the solver to take just one internal step in the direction of tBout and return.

Return value The return value flag (of type int) will be one of the following. For more details see §4.5.5.

CV\_SUCCESS CVodeB succeeded.
CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_NO\_BCK No backward problem has been added to the list of backward prob-

lems by a call to CVodeCreateB

CV\_NO\_FWD The function CVodeF has not been previously called.

CV\_ILL\_INPUT One of the inputs to CVodeB is illegal.

CV\_BAD\_ITASK The itaskB argument has an illegal value.

CV\_TOO\_MUCH\_WORK The solver took mxstep internal steps but could not reach tBout.

CV\_TOO\_MUCH\_ACC The solver could not satisfy the accuracy demanded by the user for

some internal step.

step.

CV\_CONV\_FAILURE Convergence test failures occurred too many times during one inter-

nal time step.

CV\_LSETUP\_FAIL The linear solver's setup function failed in an unrecoverable manner.

CV\_SOLVE\_FAIL The linear solver's solve function failed in an unrecoverable manner.

Notes

CV\_BCKMEM\_NULL The solver memory for the backward problem was not created with

a call to CVodeCreateB.

CV\_BAD\_TBOUT The desired output time tBout is outside the interval over which the

forward problem was solved.

CV\_REIFWD\_FAIL Reinitialization of the forward problem failed at the first checkpoint

(corresponding to the initial time of the forward problem).

CV\_FWD\_FAIL An error occurred during the integration of the forward problem.

All failure return values are negative and therefore a test flag< 0 will trap all CVodeB

failures.

In the case of multiple checkpoints and multiple backward problems, a given call to CVodeB in CV\_ONE\_STEP mode may not advance every problem one step, depending on the relative locations of the current times reached. But repeated calls will eventually advance all problems to tBout.

To obtain the solution yB to the backward problem, call the function CVodeGetB as follows:

## CVodeGetB

Call flag = CVodeGetB(cvode\_mem, which, &tret, yB);

Description The function CVodeGetB provides the solution yB of the backward ODE problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory returned by CVodeCreate.

which (int) the identifier of the backward problem.

tret (realtype) the time reached by the solver (output).

yB (N\_Vector) the backward solution at time tret.

Return value The return value flag (of type int) will be one of the following.

CV\_SUCCESS CVodeGetB was successful.

CV\_MEM\_NULL cvode\_mem is NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_ILL\_INPUT The parameter which is an invalid identifier.

Notes The user must allocate space for yB.

## 6.2.7 Adjoint sensitivity optional input

At any time during the integration of the forward problem, the user can disable the checkpointing of the forward sensitivities by calling the following function:

## CVodeAdjSetNoSensi

Call flag = CVodeAdjSetNoSensi(cvode\_mem);

Description The function CVodeAdjSetNoSensi instructs CVodeF not to save checkpointing data for

forward sensitivities anymore.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

Return value The return value flag (of type int) is one of:

CV\_SUCCESS The call to CVodeCreateB was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

### 6.2.8Optional input functions for the backward problem

### Main solver optional input functions 6.2.8.1

The adjoint module in CVODES provides wrappers for most of the optional input functions defined in §4.5.6.1. The only difference is that the user must specify the identifier which of the backward problem within the list managed by CVODES.

The optional input functions defined for the backward problem are:

```
flag = CVodeSetUserDataB(cvode_mem, which, user_dataB);
flag = CVodeSetIterTypeB(cvode_mem, which, iterB);
flag = CVodeSetMaxOrdB(cvode_mem, which, maxordB);
flag = CVodeSetMaxNumStepsB(cvode_mem, which, mxstepsB);
flag = CVodeSetInitStepB(cvode_mem, which, hinB)
flag = CVodeSetMinStepB(cvode_mem, which, hminB);
flag = CVodeSetMaxStepB(cvode_mem, which, hmaxB);
flag = CVodeSetStabLimDetB(cvode_mem, which, stldetB);
flag = CVodeSetConstraintsB(cvode_mem, which, constraintsB);
```

Their return value flag (of type int) can have any of the return values of their counterparts, but it can also be CV\_NO\_ADJ if CVodeAdjInit has not been called, or CV\_ILL\_INPUT if which was an invalid identifier.

#### 6.2.8.2Direct linear solver interface optional input functions

If using a direct linear solver interface for the Jacobian of the backward problem, the linear solver will need to be attached to the memory structure through a call to CVDlsSetLinearSolverB. The Jacobian evaluation function can be attached through a call to either CVDlsSetJacFnB or IDACVDlsSetJacFnBS, with the second used when the backward problem depends on the forwrad sensitivities.

```
CVDlsSetJacFnB
```

```
Call
             flag = CVDlsSetJacFnB(ida_mem, which, jacB);
Description
             The function CVDlsSetJacFnB specifies the Jacobian approximation function to be used
             for the backward problem.
             cvode_mem (void *) pointer to the CVODES memory returned by CVodeCreate.
Arguments
                        (int) represents the identifier of the backward problem.
             which
             jacB
                        (CVDlsJacFnB) user-defined Jacobian approximation function.
Return value The return value flag (of type int) is one of:
             CVDLS_SUCCESS
                              CVDlsSetJacFnB succeeded.
             CVDLS_MEM_NULL cvode_mem was NULL.
             CVDLS_NO_ADJ
                              The function CVodeAdjInit has not been previously called.
             CVDLS_LMEM_NULL The linear solver has not been initialized with a call to CVDlsSetLinearSolverB.
```

Notes The function type CVDlsJacFnB is described in §6.3.5.

### CVDlsSetJacFnBS

Arguments

```
Call
             flag = CVDlsSetJacFnBS(cvode_mem, which, jacBS);
            The function CVDlsSetJacFnBS specifies the Jacobian approximation function to be
Description
             used for the backward problem, in the case where the backward problem depends on
             the forward sensitivities.
             cvode_mem (void *) pointer to the CVODES memory returned by CVodeCreate.
```

CVDLS\_ILL\_INPUT The parameter which represented an invalid identifier.

which (int) represents the identifier of the backward problem.

jacBS (CVDlsJacFnBS) user-defined Jacobian approximation function.

Return value The return value flag (of type int) is one of:

CVDLS\_SUCCESS CVDlsSetJacFnBS succeeded.

CVDLS\_MEM\_NULL cvode\_mem was NULL.

CVDLS\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CVDLS\_LMEM\_NULL The linear solver has not been initialized with a call to CVDlsSetLinearSolverB.

CVDLS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes The function type CVDlsJacFnBS is described in §6.3.5.

### 6.2.8.3 SPILS linear solvers

Optional inputs for the CVSPILS linear solver module can be set for the backward problem through the following functions:

### CVSpilsSetPreconditionerB

Call flag = CVSpilsSetPreconditionerB(cvode\_mem, which, psetupB, psolveB);

Description The function CVSpilsSetPrecSolveFnB specifies the preconditioner setup and solve

functions for the backward integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

psetupB (CVSpilsPrecSetupFnB) user-defined preconditioner setup function.

psolveB (CVSpilsPrecSolveFnB) user-defined preconditioner solve function.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL cvode\_mem was NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CVSPILS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes The function types CVSpilsPrecSolveFnB and CVSpilsPrecSetupFnB are described in

§6.3.8 and §6.3.9, resp. The psetupB argument may be NULL if no setup operation is

involved in the preconditioner.

### ${\tt CVSpilsSetPreconditionerBS}$

Call flag = CVSpilsSetPreconditionerBS(cvode\_mem, which, psetupBS, psolveBS);

Description The function CVSpilsSetPrecSolveFnBS specifies the preconditioner setup and solve

functions for the backward integration, in the case where the backward problem depends

on the forward sensitivities.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

psetupBS (CVSpilsPrecSetupFnBS) user-defined preconditioner setup function.

psolveBS (CVSpilsPrecSolveFnBS) user-defined preconditioner solve function.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL cvode\_mem was NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_NO\_ADJ The function CVodeAdjInit has not been previously called. CVSPILS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes

The function types CVSpilsPrecSolveFnBS and CVSpilsPrecSetupFnBS are described in §6.3.8 and §6.3.9, resp. The psetupBS argument may be NULL if no setup operation is involved in the preconditioner.

### ${\tt CVSpilsSetJacTimesB}$

Call flag = CVSpilsSetJacTimesB(cvode\_mem, which, jsetupB, jtvB);

Description The function CVSpilsSetJacTimesB specifies the Jacobian-vector setup and product

functions to be used.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

jtsetupB (CVSpilsJacTimesSetupFnB) user-defined function to set up the Jacobian-

vector product. Pass NULL if no setup is necessary.

jtvB (CVSpilsJacTimesVecFnB) user-defined Jacobian-vector product function.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL cvode\_mem was NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CVSPILS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes The function types CVSpilsJacTimesVecFnB and CVSpilsJacTimesSetupFnB are described in §6.3.6.

### CVSpilsSetJacTimesBS

Call flag = CVSpilsSetJacTimesBS(cvode\_mem, which, jtvBS);

Description The function CVSpilsSetJacTimesBS specifies the Jacobian-vector setup and product functions to be used, in the case where the backward problem depends on the forward

sensitivities.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

jtsetupBS (CVSpilsJacTimesSetupFnBS) user-defined function to set up the Jacobian-vector product. Pass NULL if no setup is necessary.

vector product. Fass NoLL if no setup is necessary.

jtvBS (CVSpilsJacTimesVecFnBS) user-defined Jacobian-vector product function.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL cvode\_mem was NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CVSPILS\_ILL\_INPUT The parameter which represented an invalid identifier.

Notes The function types CVSpilsJacTimesVecFnBS and CVSpilsJacTimesSetupFnBS are de-

scribed in  $\S6.3.6$ .

### CVSpilsSetEpsLinB

Call flag = CVSpilsSetEpsLinB(cvode\_mem, which, eplifacB);

Description The function CVSpilsSetEpsLinB specifies the factor by which the Krylov linear solver's convergence test constant is reduced from the Newton iteration test constant. This routine can be used in both the cases wherethe backward problem does and does not

depend on the forward sensitvities.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

eplifacB (realtype) value of the convergence test constant reduction factor ( $\geq 0.0$ ).

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The optional value has been successfully set.

CVSPILS\_MEM\_NULL cvode\_mem was NULL.

CVSPILS\_LMEM\_NULL The CVSPILS linear solver has not been initialized.

CVSPILS\_NO\_ADJ The function CVodeAdjInit has not been previously called.

 ${\tt CVSPILS\_ILL\_INPUT \ The \ parameter \ which \ represented \ an \ invalid \ identifier, \ or \ {\tt eplifacB}}$ 

was negative.

Notes The default value is 0.05. Passing a value eplifacB= 0.0 also indicates using the default

value.

### 6.2.9 Optional output functions for the backward problem

The user of the adjoint module in CVODES has access to any of the optional output functions described in §4.5.8, both for the main solver and for the linear solver modules. The first argument of these CVodeGet\* and CVode\*Get\* functions is the pointer to the CVODES memory block for the backward problem. In order to call any of these functions, the user must first call the following function to obtain this pointer.

### CVodeGetAdjCVodeBmem

Call cvode\_memB = CVodeGetAdjCVodeBmem(cvode\_mem, which);

 $Description \quad The \ function \ {\tt CVodeGetAdjCVodeBmem} \ returns \ a \ pointer \ to \ the \ {\tt CVodeS} \ memory \ block$ 

for the backward problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block created by CVodeCreate.

which (int) the identifier of the backward problem.

Return value The return value, cvode\_memB (of type void \*), is a pointer to the CVODES memory for

the backward problem.

Notes The user should not modify cvode\_memB in any way.

Optional output calls should pass cvode\_memB as the first argument; for example, to get the number of integration steps: flag = CVodeGetNumSteps(cvodes\_memB, &nsteps).

To get values of the *forward* solution during a backward integration, use the following function. The input value of t would typically be equal to that at which the backward solution has just been obtained with CVodeGetB. In any case, it must be within the last checkpoint interval used by CVodeB.

### CVodeGetAdjY

Call flag = CVodeGetAdjY(cvode\_mem, t, y);

Description The function CVodeGetAdjY returns the interpolated value of the forward solution y

during a backward integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block created by CVodeCreate.

```
t (realtype) value of the independent variable at which y is desired (input).
```

y (N\_Vector) forward solution y(t).

Return value The return value flag (of type int) is one of:

CV\_SUCCESS CVodeGetAdjY was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_GETY\_BADT The value of t was outside the current checkpoint interval.

Notes The user must allocate space for y.

# ⚠

### ${\tt CVodeGetAdjCheckPointsInfo}$

Call flag = CVodeGetAdjCheckPointsInfo(cvode\_mem, CVadjCheckPointRec \*ckpnt);

Description The function CVodeGetAdjCheckPointsInfo loads an array of ncheck+1 records of type CVadjCheckPointRec. The user must allocate space for the array ckpnt.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block created by CVodeCreate.

ckpnt (CVadjCheckPointRec \*) array of ncheck+1 checkpoint records, each of
type CVadjCheckPointRec.

Return value The return value is CV\_SUCCESS if successful, or CV\_MEM\_NULL if cvode\_mem is NULL, or CV\_NO\_ADJ if ASA was not initialized.

Notes The members of each record ckpnt[i] are:

- : ckpnt[i] .my\_addr (void \*) address of current checkpoint in cvode\_mem->cv\_adj\_mem
- : ckpnt[i].next\_addr (void \*) address of next checkpoint
- : ckpnt[i].t0 (realtype) start of checkpoint interval
- : ckpnt[i].t1 (realtype) end of checkpoint interval
- : ckpnt[i].nstep (long int) step counter at ckeckpoint t0
- : ckpnt[i].order (int) method order at checkpoint t0
- : ckpnt[i].step (realtype) step size at checkpoint t0

### 6.2.10 Backward integration of quadrature equations

Not only the backward problem but also the backward quadrature equations may or may not depend on the forward sensitivities. Accordingly, either CVodeQuadInitB or CVodeQuadInitBS should be used to allocate internal memory and to initialize backward quadratures. For any other operation (extraction, optional input/output, reinitialization, deallocation), the same function is callable regardless of whether or not the quadratures are sensitivity-dependent.

### 6.2.10.1 Backward quadrature initialization functions

The function CVodeQuadInitB initializes and allocates memory for the backward integration of quadrature equations that do not depend on forward sensitivities. It has the following form:

### CVodeQuadInitB

Call flag = CVodeQuadInitB(cvode\_mem, which, rhsQB, yQBO);

Description The function CVodeQuadInitB provides required problem specifications, allocates inter-

nal memory, and initializes backward quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

rhsQB (CVQuadRhsFnB) is the C function which computes fQB, the right-hand side of the backward quadrature equations. This function has the form rhsQB(t, y, yB, qBdot, user\_dataB) (see §6.3.3).

yQBO (N\_Vector) is the value of the quadrature variables at tBO.

Return value The return value flag (of type int) will be one of the following:

 ${\tt CV\_SUCCESS} \quad \text{ The call to $\tt CVodeQuadInitB was successful.}$ 

 ${\tt CV\_MEM\_NULL} \quad {\tt cvode\_mem} \ {\tt was} \ {\tt NULL}.$ 

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_MEM\_FAIL A memory allocation request has failed.

CV\_ILL\_INPUT The parameter which is an invalid identifier.

The function CVodeQuadInitBS initializes and allocates memory for the backward integration of quadrature equations that depends on the forward sensitivities.

### CVodeQuadInitBS

Call flag = CVodeQuadInitBS(cvode\_mem, which, rhsQBS, yQBS0);

Description The function CVodeQuadInitBS provides required problem specifications, allocates internal memory, and initializes backward quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

rhsQBS (CVQuadRhsFnBS) is the C function which computes fQBS, the right-hand side of the backward quadrature equations. This function has the form rhsQBS(t, y, yS, yB, qBdot, user\_dataB) (see §6.3.4).

yQBSO (N\_Vector) is the value of the sensitivity-dependent quadrature variables at

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeQuadInitBS was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_MEM\_FAIL A memory allocation request has failed.

CV\_ILL\_INPUT The parameter which is an invalid identifier.

The integration of quadrature equations during the backward phase can be re-initialized by calling the following function. Before calling CVodeQuadReInitB for a new backward problem, call any desired solution extraction functions CVodeGet\*\* associated with the previous backward problem.

### CVodeQuadReInitB

Call flag = CVodeQuadReInitB(cvode\_mem, which, yQB0);

Description The function CVodeQuadReInitB re-initializes the backward quadrature integration.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

yQBO (N\_Vector) is the value of the quadrature variables at tBO.

Return value The return value flag (of type int) will be one of the following:

CV\_SUCCESS The call to CVodeQuadReInitB was successful.

CV\_MEM\_NULL cvode\_mem was NULL.

CV\_NO\_ADJ The function CVodeAdjInit has not been previously called.

CV\_MEM\_FAIL A memory allocation request has failed.

 $\begin{array}{ll} {\tt CV\_NO\_QUAD} & {\tt Quadrature~integration~was~not~activated~through~a~previous~call~to} \\ {\tt CVodeQuadInitB}. \end{array}$ 

CV\_ILL\_INPUT The parameter which is an invalid identifier.

Notes

The function CVodeQuadReInitB can be called after a call to either CVodeQuadInitB or CVodeQuadInitBS.

### 6.2.10.2 Backward quadrature extraction function

To extract the values of the quadrature variables at the last return time of CVodeB, CVODES provides a wrapper for the function CVodeGetQuad (see §4.7.3). The call to this function has the form

```
CVodeGetQuadB
Call
             flag = CVodeGetQuadB(cvode_mem, which, &tret, yQB);
Description
             The function CVodeGetQuadB returns the quadrature solution vector after a successful
             return from CVodeB.
Arguments
             cvode_mem (void *) pointer to the CVODES memory.
                        (realtype) the time reached by the solver (output).
                        (N_Vector) the computed quadrature vector.
             yQB
Return value The return value flag of CVodeGetQuadB is one of:
             CV_SUCCESS
                           CVodeGetQuadB was successful.
                           cvode_mem is NULL.
             CV_MEM_NULL
             CV_NO_ADJ
                           The function CVodeAdjInit has not been previously called.
             CV_NO_QUAD
                           Quadrature integration was not initialized.
             CV_BAD_DKY
                           yQB was NULL.
             CV_ILL_INPUT The parameter which is an invalid identifier.
```

### 6.2.10.3 Optional input/output functions for backward quadrature integration

Optional values controlling the backward integration of quadrature equations can be changed from their default values through calls to one of the following functions which are wrappers for the corresponding optional input functions defined in §4.7.4. The user must specify the identifier which of the backward problem for which the optional values are specified.

```
flag = CVodeSetQuadErrConB(cvode_mem, which, errconQ);
flag = CVodeQuadSStolerancesB(cvode_mem, which, reltolQ, abstolQ);
flag = CVodeQuadSVtolerancesB(cvode_mem, which, reltolQ, abstolQ);
```

Their return value flag (of type int) can have any of the return values of its counterparts, but it can also be CV\_NO\_ADJ if the function CVodeAdjInit has not been previously called or CV\_ILL\_INPUT if the parameter which was an invalid identifier.

Access to optional outputs related to backward quadrature integration can be obtained by calling the corresponding CVodeGetQuad\* functions (see §4.7.5). A pointer cvode\_memB to the CVODES memory block for the backward problem, required as the first argument of these functions, can be obtained through a call to the functions CVodeGetAdjCVodeBmem (see §6.2.9).

# 6.3 User-supplied functions for adjoint sensitivity analysis

In addition to the required ODE right-hand side function and any optional functions for the forward problem, when using the adjoint sensitivity module in CVODES, the user must supply one function defining the backward problem ODE and, optionally, functions to supply Jacobian-related information and one or two functions that define the preconditioner (if one of the CVSPILS solvers is selected) for the backward problem. Type definitions for all these user-supplied functions are given below.

### 6.3.1 ODE right-hand side for the backward problem

If the backward problem does not depend on the forward sensitivities, the user must provide a rhsB function of type CVRhsFnB defined as follows:

CVRhsFnB

Definition typedef int (\*CVRhsFnB)(realtype t, N\_Vector y,

N\_Vector yB, N\_Vector yBdot, void \*user\_dataB);

Purpose This function evaluates the right-hand side  $f_B(t, y, y_B)$  of the backward problem ODE

system. This could be either (2.19) or (2.22).

Arguments t is the current value of the independent variable.

y is the current value of the forward solution vector.

yB is the current value of the backward dependent variable vector.

yBdot is the output vector containing the right-hand side  $f_B$  of the backward

ODE problem.

user\_dataB is a pointer to user data, same as passed to CVodeSetUserDataB.

Return value A  ${\tt CVRhsFnB}$  should return 0 if successful, a positive value if a recoverable error occurred

(in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns CV\_RHSFUNC\_FAIL).

Notes Allocation of memory for yBdot is handled within CVODES.

The y, yB, and yBdot arguments are all of type N\_Vector, but yB and yBdot typically have different internal representations from y. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with respect to their N\_Vector arguments (see §7.1 and §7.2).

The user\_dataB pointer is passed to the user's rhsB function every time it is called and can be the same as the user\_data pointer used for the forward problem.

Before calling the user's rhsB function, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the right-hand side function which will halt the integration and CVodeB will return CV\_RHSFUNC\_FAIL.

# 6.3.2 ODE right-hand side for the backward problem depending on the forward sensitivities

If the backward problem does depend on the forward sensitivities, the user must provide a rhsBS function of type CVRhsFnBS defined as follows:

### CVRhsFnBS

Definition typedef int (\*CVRhsFnBS)(realtype t, N\_Vector y, N\_Vector \*yS,

N\_Vector yB, N\_Vector yBdot, void \*user\_dataB);

Purpose This function evaluates the right-hand side  $f_B(t, y, y_B, s)$  of the backward problem ODE

system. This could be either (2.19) or (2.22).

Arguments t is the current value of the independent variable.

y is the current value of the forward solution vector.

yS a pointer to an array of Ns vectors containing the sensitivities of the forward

solution.

yB is the current value of the backward dependent variable vector.

yBdot is the output vector containing the right-hand side  $f_B$  of the backward ODE problem.

user\_dataB is a pointer to user data, same as passed to CVodeSetUserDataB.

Return value A CVRhsFnBS should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns CV\_RHSFUNC\_FAIL).

Notes

Allocation of memory for qBdot is handled within CVODES.

The y, yB, and yBdot arguments are all of type N\_Vector, but yB and yBdot typically have different internal representations from y. Likewise for each yS[i]. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with respect to their N\_Vector arguments (see  $\S7.1$  and  $\S7.2$ ).

The user\_dataB pointer is passed to the user's rhsBS function every time it is called and can be the same as the user\_data pointer used for the forward problem.

Before calling the user's rhsBS function, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the right-hand side function which will halt the integration and CVodeB will return CV\_RHSFUNC\_FAIL.

### 6.3.3 Quadrature right-hand side for the backward problem

The user must provide an fQB function of type CVQuadRhsFnB defined by

### CVQuadRhsFnB

Definition typedef int (\*CVQuadRhsFnB)(realtype t, N\_Vector y, N\_Vector yB, N\_Vector qBdot, void \*user\_dataB);

Purpose This function computes the quadrature equation right-hand side for the backward problem.

Arguments

is the current value of the independent variable. t is the current value of the forward solution vector.

is the current value of the backward dependent variable vector. yВ

is the output vector containing the right-hand side fQB of the backward qBdot

quadrature equations.

user\_dataB is a pointer to user data, same as passed to CVodeSetUserDataB.

Return value A CVQuadRhsFnB should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns CV\_QRHSFUNC\_FAIL).

Notes

Allocation of memory for rhsvalBQ is handled within CVODES.

The y, yB, and qBdot arguments are all of type N\_Vector, but they typically do not all have the same representation. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with reprect to their N\_Vector arguments (see  $\S7.1$  and  $\S7.2$ ).

The user\_dataB pointer is passed to the user's fQB function every time it is called and can be the same as the user\_data pointer used for the forward problem.

Before calling the user's fQB function, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the quadrature right-hand side function which will halt the integration and CVodeB will return CV\_QRHSFUNC\_FAIL.

# 6.3.4 Sensitivity-dependent quadrature right-hand side for the backward problem

The user must provide an fQBS function of type CVQuadRhsFnBS defined by

### CVQuadRhsFnBS

Definition typedef int (\*CVQuadRhsFnBS)(realtype t, N\_Vector y, N\_Vector \*yS, N\_Vector yB, N\_Vector qBdot, void \*user\_dataB);

Purpose This function computes the quadrature equation right-hand side for the backward problem.

Arguments t is the current value of the independent variable.

y is the current value of the forward solution vector.

yS a pointer to an array of Ns vectors containing the sensitivities of the forward

solution.

yB is the current value of the backward dependent variable vector.

qBdot is the output vector containing the right-hand side fQBS of the backward

quadrature equations.

user\_dataB is a pointer to user data, same as passed to CVodeSetUserDataB.

Return value A CVQuadRhsFnBS should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns

 $CV\_QRHSFUNC\_FAIL$ ).

Notes Allocation of memory for qBdot is handled within CVODES.

The y, yS, and qBdot arguments are all of type N\_Vector, but they typically do not all have the same internal representation. Likewise for each yS[i]. It is the user's responsibility to access the vector data consistently (including the use of the correct accessor macros from each NVECTOR implementation). For the sake of computational efficiency, the vector functions in the two NVECTOR implementations provided with CVODES do not perform any consistency checks with repsect to their N\_Vector arguments (see §7.1 and §7.2).

The user\_dataB pointer is passed to the user's fQBS function every time it is called and can be the same as the user\_data pointer used for the forward problem.

Before calling the user's fQBS function, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the quadrature right-hand side function which will halt the integration and CVodeB will return CV\_QRHSFUNC\_FAIL.

# 6.3.5 Jacobian information for the backward problem (direct method Jacobian)

If the direct linear solver interface is used for the backward problem (i.e. CVDlsSetLinearSolverB is called in the step described in §6.1), the user may provide a function of type CVDlsJacFnB or CVDlsJacFnBS (see §6.2.8), defined as follows:

### CVDlsJacFnB

Definition typedef int (\*CVDlsJacFnB)(realtype t, N\_Vector y, N\_Vector yB, N\_Vector fyB, SUNMatrix JacB, void \*user\_dataB, N\_Vector tmp1B, N\_Vector tmp2B,

N\_Vector tmp3B);

Purpose This function computes the Jacobian of the backward problem (or an approximation to

it).

Arguments t is the current value of the independent variable.

y is the current value of the forward solution vector.

yB is the current value of the backward dependent variable vector. fyB is the current value of the backward right-hand side function  $f_B$ .

JacB is the output approximate Jacobian matrix.

user\_dataB is a pointer to user data - the same as passed to CVodeSetUserDataB.

tmp1B tmp2B

 ${\tt tmp3B}$  are pointers to memory allocated for variables of type  ${\tt N\_Vector}$  which can

be used by the  ${\tt CVDlsJacFnB}$  function as temporary storage or work space.

Return value A CVDlsJacFnB should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct, while CVDLS sets last\_flag to CVDLS\_JACFUNC\_RECVR), or a negative value if it failed unrecoverably (in which case the integration is halted, CVodeB returns CV\_LSETUP\_FAIL and CVDLS sets last\_flag to

CVDLS\_JACFUNC\_UNRECVR).

call to the Jacobian function.

A user-supplied Jacobian function must load the matrix JacB with an approximation to the Jacobian matrix at the point (t,y,yB), where y is the solution of the original IVP at time tt, and yB is the solution of the backward problem at the same time. Information regarding the structure of the specific SUNMATRIX structure (e.g. number of rows, upper/lower bandwidth, sparsity type) may be obtained through using the implementation-specific SUNMATRIX interface functions (see Chapter 8 for details). Only nonzero elements need to be loaded into JacB as this matrix is set to zero before the

Before calling the user's CVDlsJacFnB, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the Jacobian function which will halt the integration (CVodeB returns CV\_LSETUP\_FAIL and CVDLS sets last\_flag to CVDLS\_JACFUNC\_UNRECVR).

### CVDlsJacFnBS

Notes

Definition typedef int (\*CVDlsJacFnBS)(realtype t, N\_Vector y,

N\_Vector \*yS, N\_Vector yB, N\_Vector fyB, SUNMatrix JacB, void \*user\_dataB, N\_Vector tmp1B, N\_Vector tmp2B, N\_Vector tmp3B);

Purpose This function computes the Jacobian of the backward problem (or an approximation to it), in the case where the backward problem depends on the forward sensitivities.

Arguments t is the current value of the independent variable.

y is the current value of the forward solution vector.

yS a pointer to an array of Ns vectors containing the sensitivities of the forward solution.

yB is the current value of the backward dependent variable vector. fyB is the current value of the backward right-hand side function  $f_B$ .

JacB is the output approximate Jacobian matrix.

user\_dataB is a pointer to user data - the same as passed to CVodeSetUserDataB.

tmp1B tmp2B

tmp3B are pointers to memory allocated for variables of type N\_Vector which can

be used by CVDlsJacFnBS as temporary storage or work space.

Return value A CVDlsJacFnBS should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct, while CVDLS sets last\_flag to CVDLS\_JACFUNC\_RECVR), or a negative value if it failed unrecoverably (in which case the integration is halted, CVodeB returns CV\_LSETUP\_FAIL and CVDLS sets last\_flag to CVDLS\_JACFUNC\_UNRECVR).

Notes

A user-supplied Jacobian function must load the matrix JacB with an approximation to the Jacobian matrix at the point (t,y,yS,yB), where y is the solution of the original IVP at time tt, yS is the vector of forward sensitivities at time tt, and yB is the solution of the backward problem at the same time. Information regarding the structure of the specific SUNMATRIX structure (e.g. number of rows, upper/lower bandwidth, sparsity type) may be obtained through using the implementation-specific SUNMATRIX interface functions (see Chapter 8 for details). Only nonzero elements need to be loaded into JacB as this matrix is set to zero before the call to the Jacobian function.

Before calling the user's CVDlsDenseJacFnBS, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the Jacobian function which will halt the integration (CVodeB returns CV\_LSETUP\_FAIL and CVDLS sets last\_flag to CVDLS\_JACFUNC\_UNRECVR).

# 6.3.6 Jacobian information for the backward problem (matrix-vector product)

If the CVSPILS solver interface is selected for the backward problem (i.e., CVSpilsSetLinearSolverB is called in the steps described in  $\S 6.1$ ), the user may provide a function of type CVSpilsJacTimesVecFnB or CVSpilsJacTimesVecFnBS in the following form, to compute matrix-vector products Jv. If such a function is not supplied, the default is a difference quotient approximation to these products.

### ${\tt CVSpilsJacTimesVecFnB}$

Definition typedef int (\*CVSpilsJacTimesVecFnB)(N\_Vector vB, N\_Vector JvB, realtype t, N\_Vector y, N\_Vector yB, N\_Vector fyB, void \*user\_dataB, N\_Vector tmpB);

Purpose This function computes the action of the Jacobian JB for the backward problem on a given vector vB.

Arguments vB is the vector by which the Jacobian must be multiplied to the right.

JvB is the computed output vector JB\*vB.

t is the current value of the independent variable.y is the current value of the forward solution vector.

yB is the current value of the backward dependent variable vector. fyB is the current value of the backward right-hand side function  $f_B$ . user\_dataB is a pointer to user data – the same as passed to CVodeSetUserDataB.

tmpB is a pointer to memory allocated for a variable of type N\_Vector which can be used by CVSpilsJacTimesVecFn as temporary storage or work space.

Return value The return value of a function of type CVSpilsJtimesVecFnB should be 0 if successful or nonzero if an error was encountered, in which case the integration is halted.

Notes

A user-supplied Jacobian-vector product function must load the vector JvB with the product of the Jacobian of the backward problem at the point (t,y,yB) and the vector vB. Here, y is the solution of the original IVP at time t and yB is the solution of the backward problem at the same time. The rest of the arguments are equivalent to those passed to a function of type CVSpilsJacTimesVecFn (see §4.6.6). If the backward problem is the adjoint of  $\dot{y} = f(t,y)$ , then this function is to compute  $-(\partial f/\partial y)^T v_B$ .

### ${\tt CVSpilsJacTimesVecFnBS}$

vΒ

```
Definition typedef int (*CVSpilsJacTimesVecFnBS)(N_Vector vB, N_Vector JvB, realtype t, N_Vector y, N_Vector *yS, N_Vector yB, N_Vector fyB, void *user_dataB, N_Vector tmpB);
```

Purpose

This function computes the action of the Jacobian JB for the backward problem on a given vector vB, in the case where the backward problem depends on the forward sensitivities.

Arguments

is the vector by which the Jacobian must be multiplied to the right.

JvB is the computed output vector JB\*vB.

t is the current value of the independent variable.

y is the current value of the forward solution vector.

ys is a pointer to an array containing the forward sensitivity vectors.

yB is the current value of the backward dependent variable vector.

fyB is the current value of the backward right-hand side function  $f_B$ .

user\_dataB is a pointer to user data - the same as passed to CVodeSetUserDataB.

tmpB is a pointer to memory allocated for a variable of type N\_Vector which can be used by CVSpilsJacTimesVecFn as temporary storage or work space.

Return value The return value of a function of type CVSpilsJtimesVecFnBS should be 0 if successful or nonzero if an error was encountered, in which case the integration is halted.

Notes

A user-supplied Jacobian-vector product function must load the vector JvB with the product of the Jacobian of the backward problem at the point (t,y, yB) and the vector vB. Here, y is the solution of the original IVP at time t and yB is the solution of the backward problem at the same time. The rest of the arguments are equivalent to those passed to a function of type CVSpilsJacTimesVecFn (see §4.6.6).

### 6.3.7 Jacobian information for the backward problem (matrix-vector setup)

If the user's Jacobian-times-vector requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied function of type CVSpilsJacTimesSetupFnB, defined as follows:

### CVSpilsJacTimesSetupFnB

Purpose This function preprocesses and/or evaluates Jacobian data needed by the Jacobian-times-vector routine for the backward problem.

Arguments is the current value of the independent variable. t

> is the current value of the dependent variable vector, y(t). у

yВ is the current value of the backward dependent variable vector.

fyB is the current value of the right-hand-side for the backward problem.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed to CVSetUserDataB.

Return value The value returned by the Jacobian-vector setup function should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

Notes

Each call to the Jacobian-vector setup function is preceded by a call to the backward problem residual user function with the same (t,y, yB) arguments. Thus, the setup function can use any auxiliary data that is computed and saved during the evaluation of the right-hand-side function.

If the user's CVSpilsJacTimesVecFnB function uses difference quotient approximations, it may need to access quantities not in the call list. These include the current stepsize, the error weights, etc. To obtain these, the user will need to add a pointer to cvode\_mem to user\_dataB and then use the CVGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

### ${\tt CVSpilsJacTimesSetupFnBS}$

Definition typedef int (\*CVSpilsJacTimesSetupFnBS)(realtype t,

> N\_Vector y, N\_Vector \*yS, N\_Vector yB, N\_Vector fyB, void \*user\_dataB);

Purpose

This function preprocesses and/or evaluates Jacobian data needed by the Jacobiantimes-vector routine for the backward problem, in the case that the backward problem depends on the forward sensitivities.

Arguments

is the current value of the independent variable.

is the current value of the dependent variable vector, y(t). У

yS a pointer to an array of Ns vectors containing the sensitivities of the forward

solution.

is the current value of the backward dependent variable vector. yВ

fyB is the current value of the right-hand-side function for the backward problem.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed to CVSetUserDataB.

Return value The value returned by the Jacobian-vector setup function should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

Notes

Each call to the Jacobian-vector setup function is preceded by a call to the backward problem residual user function with the same (t,y, yS, yB) arguments. Thus, the setup function can use any auxiliary data that is computed and saved during the evaluation of the right-hand-side function.

If the user's CVSpilsJacTimesVecFnB function uses difference quotient approximations, it may need to access quantities not in the call list. These include the current stepsize, the error weights, etc. To obtain these, the user will need to add a pointer to cvode\_mem to user\_dataB and then use the CVGet\* functions described in §4.5.8.2. The unit roundoff can be accessed as UNIT\_ROUNDOFF defined in sundials\_types.h.

### 6.3.8 Preconditioning for the backward problem (linear system solution)

If preconditioning is used during integration of the backward problem, then the user must provide a C function to solve the linear system Pz=r, where P may be either a left or a right preconditioner matrix. Here P should approximate (at least crudely) the Newton matrix  $M_B=I-\gamma_BJ_B$ , where  $J_B=\partial f_B/\partial y_B$ . If preconditioning is done on both sides, the product of the two preconditioner matrices should approximate  $M_B$ . This function must be of one of the following two types:

### CVSpilsPrecSolveFnB

Definition typedef int (\*CVSpilsPrecSolveFnB)(realtype t, N\_Vector y, N\_Vector yB, N\_Vector fyB, N\_Vector rvecB, N\_Vector zvecB, realtype gammaB, realtype deltaB, void \*user\_dataB); Purpose This function solves the preconditioning system Pz = r for the backward problem. Arguments is the current value of the independent variable. is the current value of the forward solution vector. у is the current value of the backward dependent variable vector. yВ fyB is the current value of the backward right-hand side function  $f_B$ . is the right-hand side vector r of the linear system to be solved. rvecB zvecB is the computed output vector. gammaB is the scalar appearing in the Newton matrix,  $M_B = I - \gamma_B J_B$ . deltaB is an input tolerance to be used if an iterative method is employed in the solution. user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed

Return value The return value of a preconditioner solve function for the backward problem should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

to CVodeSetUserDataB.

### CVSpilsPrecSolveFnBS

Definition	typedef in	<pre>nt (*CVSpilsPrecSolveFnBS)(realtype t, N_Vector y, N_Vector *yS,</pre>
Purpose	This function solves the preconditioning system $Pz = r$ for the backward problem, in the case where the backward problem depends on the forward sensitivities.	
Arguments	t	is the current value of the independent variable.
	У	is the current value of the forward solution vector.
	уS	is a pointer to an array containing the forward sensitivity vectors.
	уВ	is the current value of the backward dependent variable vector.
	fyB	is the current value of the backward right-hand side function $f_B$ .
	rvecB	is the right-hand side vector $r$ of the linear system to be solved.
	zvecB	is the computed output vector.
	gammaB	is the scalar appearing in the Newton matrix, $M_B = I - \gamma_B J_B$ .
	deltaB	is an input tolerance to be used if an iterative method is employed in the solution.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed to CVodeSetUserDataB.

Return value The return value of a preconditioner solve function for the backward problem should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

### 6.3.9 Preconditioning for the backward problem (Jacobian data)

If the user's preconditioner requires that any Jacobian-related data be preprocessed or evaluated, then this needs to be done in a user-supplied C function of one of the following two types:

### CVSpilsPrecSetupFnB

Definition typedef int (\*CVSpilsPrecSetupFnB)(realtype t, N\_Vector y, N\_Vector yB, N\_Vector fyB, booleantype jokB, booleantype \*jcurPtrB, realtype gammaB, void \*user\_dataB); Purpose This function preprocesses and/or evaluates Jacobian-related data needed by the preconditioner for the backward problem. The arguments of a CVSpilsPrecSetupFnB are as follows: Arguments is the current value of the independent variable. is the current value of the forward solution vector. у vΒ is the current value of the backward dependent variable vector. is the current value of the backward right-hand side function  $f_B$ . fyB is an input flag indicating whether Jacobian-related data needs to be recomjokB

can be safely used (jokB=SUNTRUE).

jcurPtr is an output flag which must be set to SUNTRUE if Jacobian-relatd data was

puted (jokB=SUNFALSE) or information saved from a previous invokation

recomputed or SUNFALSE otherwise.

gammaB is the scalar appearing in the Newton matrix.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed
to CVodeSetUserDataB.

Return value The return value of a preconditioner setup function for the backward problem should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

### CVSpilsPrecSetupFnBS

Definition typedef int (\*CVSpilsPrecSetupFnBS)(realtype t, N\_Vector y, N\_Vector \*yS, N\_Vector yB, N\_Vector fyB, booleantype jokB, booleantype \*jcurPtrB, realtype gammaB, void \*user\_dataB);

Purpose This function preprocesses and/or evaluates Jacobian-related data needed by the preconditioner for the backward problem, in the case where the backward problem depends on the forward sensitivities.

Arguments The arguments of a CVSpilsPrecSetupFnBS are as follows:

t is the current value of the independent variable.

y is the current value of the forward solution vector.

yS is a pointer to an array containing the forward sensitivity vectors.

yB is the current value of the backward dependent variable vector.

fyB is the current value of the backward right-hand side function  $f_B$ .

jokB is an input flag indicating whether Jacobian-related data needs to be recomputed (jokB=SUNFALSE) or information saved from a previous invokation

can be safely used (jokB=SUNTRUE).

jcurPtr is an output flag which must be set to SUNTRUE if Jacobian-relatd data was

recomputed or SUNFALSE otherwise.

gammaB is the scalar appearing in the Newton matrix.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed to CVodeSetUserDataB.

Return value The return value of a preconditioner setup function for the backward problem should be 0 if successful, positive for a recoverable error (in which case the step will be retried), or negative for an unrecoverable error (in which case the integration is halted).

# 6.4 Using CVODES preconditioner modules for the backward problem

As on the forward integration phase, the efficiency of Krylov iterative methods for the solution of linear systems can be greatly enhanced through preconditioning. Both preconditioner modules provided with SUNDIALS, the serial banded preconditioner CVBANDPRE and the parallel band-block-diagonal preconditioner module CVBBDPRE, provide interface functions through which they can be used on the backward integration phase.

### 6.4.1 Using the banded preconditioner CVBANDPRE

The adjoint module in CVODES offers an interface to the banded preconditioner module CVBANDPRE described in section §4.8.1. This preconditioner, usable only in a serial setting, provides a band matrix preconditioner based on difference quotients of the backward problem right-hand side function fB. It generates a banded approximation to the Jacobian with  $m_{lB}$  sub-diagonals and  $m_{uB}$  super-diagonals to be used with one of the Krylov linear solvers.

In order to use the CVBANDPRE module in the solution of the backward problem, the user need not define any additional functions. Instead, *after* one of the CVSPILS linear solvers has been specified, by calling the appropriate function (see §6.2.5), the following call to the CVBANDPRE module initialization function must be made.

### CVBandPrecInitB

Call flag = CVBandPrecInitB(cvode\_mem, which, nB, muB, mlB);

Description The function CVBandPrecInitB initializes and allocates memory for the CVBANDPRE preconditioner for the backward problem. It creates, allocates, and stores (internally in the CVODES solver block) a pointer to the newly created CVBANDPRE memory block.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block.

which (int) the identifier of the backward problem.

nB (sunindextype) backward problem dimension.

muB (sunindextype) upper half-bandwidth of the backward problem Jacobian

approximation.

 $\verb|mlB| \qquad \qquad (\verb|sunindextype|) \ lower \ half-bandwidth \ of \ the \ backward \ problem \ Jacobian$ 

approximation.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The call to CVodeBandPrecInitB was successful.

CVSPILS\_MEM\_FAIL A memory allocation request has failed.

```
CVSPILS_MEM_NULL The cvode_mem argument was NULL.

CVSPILS_LMEM_NULL No linear solver has been attached.

CVSPILS_ILL_INPUT An invalid parameter has been passed.
```

For more details on CVBANDPRE see §4.8.1.

### 6.4.2 Using the band-block-diagonal preconditioner CVBBDPRE

The adjoint module in CVODES offers an interface to the band-block-diagonal preconditioner module CVBBDPRE described in section §4.8.2. This generates a preconditioner that is a block-diagonal matrix with each block being a band matrix and can be used with one of the Krylov linear solvers and with the MPI-parallel vector module NVECTOR\_PARALLEL.

In order to use the CVBBDPRE module in the solution of the backward problem, the user must define one or two additional functions, described at the end of this section.

### 6.4.2.1 Initialization of CVBBDPRE

CVSPILS\_SUCCESS

The CVBBDPRE module is initialized by calling the following function, after one of the CVSPILS linear solvers has been specified by calling the appropriate function (see §6.2.5).

```
CVBBDPrecInitB
             flag = CVBBDPrecInitB(cvode_mem, which, NlocalB, mudqB, mldqB,
Call
                                      mukeepB, mlkeepB, dqrelyB, glocB, gcommB);
Description
             The function CVBBDPrecInitB initializes and allocates memory for the CVBBDPRE pre-
             conditioner for the backward problem. It creates, allocates, and stores (internally in
             the CVODES solver block) a pointer to the newly created CVBBDPRE memory block.
Arguments
             cvode_mem (void *) pointer to the CVODES memory block.
             which
                        (int) the identifier of the backward problem.
             NlocalB
                        (sunindextype) local vector dimension for the backward problem.
             mudaB
                        (sunindextype) upper half-bandwidth to be used in the difference-quotient
                        Jacobian approximation.
                        (sunindextype) lower half-bandwidth to be used in the difference-quotient
             mldqB
                        Jacobian approximation.
             mukeepB
                        (sunindextype) upper half-bandwidth of the retained banded approximate
                        Jacobian block.
                        (sunindextype) lower half-bandwidth of the retained banded approximate
             mlkeepB
                        Jacobian block.
             dqrelyB
                        (realtype) the relative increment in components of yB used in the difference
                        quotient approximations. The default is dgrelyB = \sqrt{unit roundoff}, which
                        can be specified by passing dqrely = 0.0.
             glocB
                        (CVBBDLocalFnB) the C function which computes the function g_B(t, y, y_B)
                        approximating the right-hand side of the backward problem.
                        (CVBBDCommFnB) the optional C function which performs all interprocess
             gcommB
                        communication required for the computation of g_B.
Return value The return value flag (of type int) is one of:
```

To reinitialize the CVBBDPRE preconditioner module for the backward problem, possibly with changes in mudqB, mldqB, or dqrelyB, call the following function:

CVSPILS\_MEM\_FAIL A memory allocation request has failed.

CVSPILS\_MEM\_NULL The cvode\_mem argument was NULL.

CVSPILS\_LMEM\_NULL No linear solver has been attached.

CVSPILS\_ILL\_INPUT An invalid parameter has been passed.

The call to CVodeBBDPrecInitB was successful.

### CVBBDPrecReInitB

Call flag = CVBBDPrecReInitB(cvode\_mem, which, mudqB, mldqB, dqrelyB);

Description The function CVBBDPrecReInitB reinitializes the CVBBDPRE preconditioner for the

backward problem.

Arguments cvode\_mem (void \*) pointer to the CVODES memory block returned by CVodeCreate.

which (int) the identifier of the backward problem.

mudqB (sunindextype) upper half-bandwidth to be used in the difference-quotient

Jacobian approximation.

mldqB (sunindextype) lower half-bandwidth to be used in the difference-quotient

Jacobian approximation.

dqrelyB (realtype) the relative increment in components of yB used in the difference

quotient approximations.

Return value The return value flag (of type int) is one of:

CVSPILS\_SUCCESS The call to CVodeBBDPrecReInitB was successful.

CVSPILS\_MEM\_FAIL A memory allocation request has failed.

CVSPILS\_MEM\_NULL The cvode\_mem argument was NULL.

CVSPILS\_PMEM\_NULL The CVodeBBDPrecInitB has not been previously called.

CVSPILS\_LMEM\_NULL No linear solver has been attached.

CVSPILS\_ILL\_INPUT An invalid parameter has been passed.

For more details on CVBBDPRE see  $\S4.8.2$ .

### 6.4.2.2 User-supplied functions for CVBBDPRE

To use the CVBBDPRE module, the user must supply one or two functions which the module calls to construct the preconditioner: a required function glocB (of type CVBBDLocalFnB) which approximates the right-hand side of the backward problem and which is computed locally, and an optional function gcommB (of type CVBBDCommFnB) which performs all interprocess communication necessary to evaluate this approximate right-hand side (see §4.8.2). The prototypes for these two functions are described below.

### CVBBDLocalFnB

Definition typedef int (\*CVBBDLocalFnB)(sunindextype NlocalB, realtype t, N\_Vector y, N\_Vector yB, N\_Vector gB, void \*user\_dataB);

Purpose This glocB function loads the vector gB, an approximation to the right-hand side  $f_B$  of the backward problem, as a function of t, y, and yB.

Arguments NlocalB is the local vector length for the backward problem.

t is the value of the independent variable.

y is the current value of the forward solution vector.

yB is the current value of the backward dependent variable vector.

gB is the output vector,  $g_B(t, y, y_B)$ .

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed to CVodeSetUserDataB.

Return value An CVBBDLocalFnB should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns CV\_LSETUP\_FAIL).

Notes This routine must assume that all interprocess communication of data needed to calculate gB has already been done, and this data is accessible within user\_dataB.

Before calling the user's CVBBDLocalFnB, CVODES needs to evaluate (through interpolation) the values of the states from the forward integration. If an error occurs in the interpolation, CVODES triggers an unrecoverable failure in the preconditioner setup function which will halt the integration (CVodeB returns CV\_LSETUP\_FAIL).

### CVBBDCommFnB

Notes

Definition typedef int (\*CVBBDCommFnB)(sunindextype NlocalB, realtype t, N\_Vector y, N\_Vector yB, void \*user\_dataB);

Purpose This gcommB function must perform all interprocess communications necessary for the execution of the glocB function above, using the input vectors y and yB.

Arguments NlocalB is the local vector length.

t is the value of the independent variable.

y is the current value of the forward solution vector.

yB is the current value of the backward dependent variable vector.

user\_dataB is a pointer to user data — the same as the user\_dataB parameter passed

 $to~{\tt CVodeSetUserDataB}.$ 

Return value An CVBBDCommFnB should return 0 if successful, a positive value if a recoverable error occurred (in which case CVODES will attempt to correct), or a negative value if it failed unrecoverably (in which case the integration is halted and CVodeB returns CV\_LSETUP\_FAIL).

The gcommB function is expected to save communicated data in space defined within the structure user\_dataB.

Each call to the gcommB function is preceded by a call to the function that evaluates the right-hand side of the backward problem with the same t, y, and yB, arguments. If there is no additional communication needed, then pass gcommB = NULL to CVBBDPrecInitB.

# Chapter 7

# Description of the NVECTOR module

The SUNDIALS solvers are written in a data-independent manner. They all operate on generic vectors (of type N\_Vector) through a set of operations defined by the particular NVECTOR implementation. Users can provide their own specific implementation of the NVECTOR module, or use one of the implementations provided with SUNDIALS. The generic operations are described below and the implementations provided with SUNDIALS are described in the following sections.

The generic N\_Vector type is a pointer to a structure that has an implementation-dependent content field containing the description and actual data of the vector, and an ops field pointing to a structure with generic vector operations. The type N\_Vector is defined as

```
typedef struct _generic_N_Vector *N_Vector;
struct _generic_N_Vector {
    void *content;
    struct _generic_N_Vector_Ops *ops;
};
```

The \_generic\_N\_Vector\_Ops structure is essentially a list of pointers to the various actual vector operations, and is defined as

```
struct _generic_N_Vector_Ops {
  N_Vector_ID (*nvgetvectorid)(N_Vector);
  N_Vector
              (*nvclone)(N_Vector);
  N_Vector
              (*nvcloneempty)(N_Vector);
  void
              (*nvdestroy)(N_Vector);
              (*nvspace)(N_Vector, sunindextype *, sunindextype *);
  void
              (*nvgetarraypointer)(N_Vector);
  realtype*
              (*nvsetarraypointer)(realtype *, N_Vector);
  void
              (*nvlinearsum)(realtype, N_Vector, realtype, N_Vector, N_Vector);
  void
              (*nvconst)(realtype, N_Vector);
  void
  void
              (*nvprod)(N_Vector, N_Vector, N_Vector);
              (*nvdiv)(N_Vector, N_Vector, N_Vector);
  void
              (*nvscale)(realtype, N_Vector, N_Vector);
  void
  void
              (*nvabs)(N_Vector, N_Vector);
              (*nvinv)(N_Vector, N_Vector);
  void
  void
              (*nvaddconst)(N_Vector, realtype, N_Vector);
  realtype
              (*nvdotprod)(N_Vector, N_Vector);
  realtype
              (*nvmaxnorm)(N_Vector);
  realtype
              (*nvwrmsnorm)(N_Vector, N_Vector);
```

```
realtype (*nvwrmsnormmask)(N_Vector, N_Vector);
realtype (*nvwin)(N_Vector);
realtype (*nvwl2norm)(N_Vector, N_Vector);
realtype (*nvl1norm)(N_Vector);
void (*nvcompare)(realtype, N_Vector, N_Vector);
booleantype (*nvinvtest)(N_Vector, N_Vector);
booleantype (*nvconstrmask)(N_Vector, N_Vector, N_Vector);
realtype (*nvminquotient)(N_Vector, N_Vector);
};
```

The generic NVECTOR module defines and implements the vector operations acting on N\_Vector. These routines are nothing but wrappers for the vector operations defined by a particular NVECTOR implementation, which are accessed through the *ops* field of the N\_Vector structure. To illustrate this point we show below the implementation of a typical vector operation from the generic NVECTOR module, namely N\_VScale, which performs the scaling of a vector x by a scalar c:

```
void N_VScale(realtype c, N_Vector x, N_Vector z)
{
   z->ops->nvscale(c, x, z);
}
```

Table 7.2 contains a complete list of all vector operations defined by the generic NVECTOR module.

Finally, note that the generic NVECTOR module defines the functions N\_VCloneVectorArray and N\_VCloneVectorArrayEmpty. Both functions create (by cloning) an array of count variables of type N\_Vector, each of the same type as an existing N\_Vector. Their prototypes are

```
N_Vector *N_VCloneVectorArray(int count, N_Vector w);
N_Vector *N_VCloneVectorArrayEmpty(int count, N_Vector w);
```

and their definitions are based on the implementation-specific N\_VClone and N\_VCloneEmpty operations, respectively.

An array of variables of type  $N_{\text{-}}Vector$  can be destroyed by calling  $N_{\text{-}}VDestroyVectorArray$ , whose prototype is

```
void N_VDestroyVectorArray(N_Vector *vs, int count);
```

and whose definition is based on the implementation-specific N\_VDestroy operation.

A particular implementation of the NVECTOR module must:

- Specify the *content* field of N\_Vector.
- Define and implement the vector operations. Note that the names of these routines should be unique to that implementation in order to permit using more than one NVECTOR module (each with different N\_Vector internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free an N\_Vector with the new *content* field and with *ops* pointing to the new vector operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined N\_Vector (e.g., a routine to print the content for debugging purposes).
- Optionally, provide accessor macros as needed for that particular implementation to be used to access different parts in the *content* field of the newly defined N\_Vector.

Each NVECTOR implementation included in SUNDIALS has a unique identifier specified in enumeration and shown in Table 7.1. It is recommended that a user-supplied NVECTOR implementation use the SUNDIALS\_NVEC\_CUSTOM identifier.

Table 7.1: Vector Identifications associated with vector kernels supplied with SUNDIALS.

Vector ID	Vector type	ID Value
SUNDIALS_NVEC_SERIAL	Serial	0
SUNDIALS_NVEC_PARALLEL	Distributed memory parallel (MPI)	1
SUNDIALS_NVEC_OPENMP	OpenMP shared memory parallel	2
SUNDIALS_NVEC_PTHREADS	PThreads shared memory parallel	3
SUNDIALS_NVEC_PARHYP	hypre ParHyp parallel vector	4
SUNDIALS_NVEC_PETSC	PETSc parallel vector	5
SUNDIALS_NVEC_CUSTOM	User-provided custom vector	6

Table 7.2: Description of the NVECTOR operations

Name	Usage and Description
N_VGetVectorID	<pre>id = N_VGetVectorID(w); Returns the vector type identifier for the vector w. It is used to determine the vector implementation type (e.g. serial, parallel,) from the abstract N_Vector interface. Returned values are given in Table 7.1.</pre>
N_VClone	<pre>v = N_VClone(w); Creates a new N_Vector of the same type as an existing vector w and sets the ops field. It does not copy the vector, but rather allocates storage for the new vector.</pre>
N_VCloneEmpty	<pre>v = N_VCloneEmpty(w); Creates a new N_Vector of the same type as an existing vector w and sets the ops field. It does not allocate storage for data.</pre>
N_VDestroy	N_VDestroy(v); Destroys the N_Vector v and frees memory allocated for its internal data.
N_VSpace	N_VSpace(nvSpec, &lrw, &liw); Returns storage requirements for one N_Vector. lrw contains the number of realtype words and liw contains the number of integer words. This function is advisory only, for use in determining a user's total space requirements; it could be a dummy function in a user-supplied NVECTOR module if that information is not of interest.
	continued on next page

continued from last page		
Name	Usage and Description	
N_VGetArrayPointer	vdata = N_VGetArrayPointer(v); Returns a pointer to a realtype array from the N_Vector v. Note that this assumes that the internal data in N_Vector is a contiguous array of realtype. This routine is only used in the solver-specific interfaces to the dense and banded (serial) linear solvers, the sparse linear solvers (serial and threaded), and in the interfaces to the banded (serial) and band-block-diagonal (parallel) preconditioner modules provided with SUNDIALS.	
N_VSetArrayPointer	N_VSetArrayPointer(vdata, v); Overwrites the data in an N_Vector with a given array of realtype. Note that this assumes that the internal data in N_Vector is a contiguous array of realtype. This routine is only used in the interfaces to the dense (serial) linear solver, hence need not exist in a user-supplied NVECTOR module for a parallel environment.	
N_VLinearSum	N_VLinearSum(a, x, b, y, z); Performs the operation $z = ax + by$ , where $a$ and $b$ are realtype scalars and $x$ and $y$ are of type N_Vector: $z_i = ax_i + by_i$ , $i = 0, \ldots, n-1$ .	
N_VConst	N_VConst(c, z); Sets all components of the N_Vector z to realtype c: $z_i=c,i=0,\ldots,n-1.$	
N_VProd	N_VProd(x, y, z); Sets the N_Vector z to be the component-wise product of the N_Vector inputs x and y: $z_i = x_i y_i$ , $i = 0, \ldots, n-1$ .	
N_VDiv	N_VDiv(x, y, z); Sets the N_Vector z to be the component-wise ratio of the N_Vector inputs x and y: $z_i = x_i/y_i$ , $i = 0, \ldots, n-1$ . The $y_i$ may not be tested for 0 values. It should only be called with a y that is guaranteed to have all nonzero components.	
N_VScale	N_VScale(c, x, z); Scales the N_Vector x by the realtype scalar c and returns the result in z: $z_i = cx_i$ , $i = 0, \ldots, n-1$ .	
N_VAbs	N_VAbs(x, z); Sets the components of the N_Vector z to be the absolute values of the components of the N_Vector x: $y_i =  x_i , i = 0, \ldots, n-1$ .

Name	Usage and Description	
N_VInv	N_VInv(x, z); Sets the components of the N_Vector z to be the inverses of the components of the N_Vector x: $z_i = 1.0/x_i$ , $i = 0, \ldots, n-1$ . This routine may not check for division by 0. It should be called only with an x which is guaranteed to have all nonzero components.	
$N_{-}VAddConst$	N_VAddConst(x, b, z); Adds the realtype scalar b to all components of x and returns the result in the N_Vector z: $z_i = x_i + b$ , $i = 0, \ldots, n-1$ .	
$N_VDotProd$	d = N_VDotProd(x, y); Returns the value of the ordinary dot product of x and y: $d = \sum_{i=0}^{n-1} x_i y_i$ .	
N_VMaxNorm	m = N_VMaxNorm(x); Returns the maximum norm of the N_Vector x: $m = \max_i  x_i $ .	
N_VWrmsNorm	m = N_VWrmsNorm(x, w) Returns the weighted root-mean-square norm of the N_Vector x with realtype weight vector w: $m = \sqrt{\left(\sum_{i=0}^{n-1} (x_i w_i)^2\right)/n}$ .	
N_VWrmsNormMask	m = N_VWrmsNormMask(x, w, id); Returns the weighted root mean square norm of the N_Vector x with realtype weight vector w built using only the elements of x corresponding to positive elements of the N_Vector id: $m = \sqrt{\left(\sum_{i=0}^{n-1} (x_i w_i m s k_i)^2\right)/n}, \text{ where } m s k_i \text{ is } 1 \text{ if } id_i > 0 \text{ or } 0 \text{ if } id_i \leq 0.$	
$N_{-}VMin$	$m = N_{\nu} \text{VMin}(x);$ Returns the smallest element of the N_Vector x: $m = \min_i x_i$ .	
N_VWL2Norm	m = N_VWL2Norm(x, w); Returns the weighted Euclidean $\ell_2$ norm of the N_Vector x with realtype weight vector w: $m = \sqrt{\sum_{i=0}^{n-1} (x_i w_i)^2}$ .	
N_VL1Norm	m = N_VL1Norm(x); Returns the $\ell_1$ norm of the N_Vector x: $m = \sum_{i=0}^{n-1}  x_i $ .	
N_VCompare	N_VCompare(c, x, z); Compares the components of the N_Vector x to the realtype scalar c and returns an N_Vector z such that: $z_i = 1.0$ if $ x_i  \ge c$ and $z_i = 0.0$ otherwise.	
	continued on next page	

continued from last page		
Name	Usage and Description	
N_VInvTest	t = N_VInvTest(x, z); Sets the components of the N_Vector z to be the inverses of the components of the N_Vector x, with prior testing for zero values: $z_i = 1.0/x_i$ , $i = 0, \ldots, n-1$ . This routine returns a boolean assigned to SUNTRUE if all components of x are nonzero (successful inversion) and returns SUNFALSE otherwise.	
N_VConstrMask	t = N_VConstrMask(c, x, m); Performs the following constraint tests: $x_i > 0$ if $c_i = 2$ , $x_i \geq 0$ if $c_i = 1$ , $x_i \leq 0$ if $c_i = -1$ , $x_i < 0$ if $c_i = -2$ . There is no constraint on $x_i$ if $c_i = 0$ . This routine returns a boolean assigned to SUNFALSE if any element failed the constraint test and assigned to SUNTRUE if all passed. It also sets a mask vector m, with elements equal to 1.0 where the constraint test failed, and 0.0 where the test passed. This routine is used only for constraint checking.	
$N_{-}VMinQuotient$	minq = N_VMinQuotient(num, denom); This routine returns the minimum of the quotients obtained by termwise dividing num; by denom;. A zero element in denom will be skipped.  If no such quotients are found, then the large value BIG_REAL (defined in the header file sundials_types.h) is returned.	

## 7.1 The NVECTOR\_SERIAL implementation

The serial implementation of the NVECTOR module provided with SUNDIALS, NVECTOR\_SERIAL, defines the *content* field of N\_Vector to be a structure containing the length of the vector, a pointer to the beginning of a contiguous data array, and a boolean flag *own\_data* which specifies the ownership of *data*.

```
struct _N_VectorContent_Serial {
   sunindextype length;
   booleantype own_data;
   realtype *data;
};
```

The header file to include when using this module is nvector\_serial.h. The installed module library to link to is libsundials\_nvecserial.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR\_SERIAL vector. The suffix \_S in the names denotes the serial version.

### • NV\_CONTENT\_S

This routine gives access to the contents of the serial vector N\_Vector.

The assignment  $v\_cont = NV\_CONTENT\_S(v)$  sets  $v\_cont$  to be a pointer to the serial  $N\_Vector$  content structure.

Implementation:

```
#define NV_CONTENT_S(v) ( (N_VectorContent_Serial)(v->content) )
```

• NV\_OWN\_DATA\_S, NV\_DATA\_S, NV\_LENGTH\_S

These macros give individual access to the parts of the content of a serial N\_Vector.

The assignment  $v_{data} = NV_DATA_S(v)$  sets  $v_{data}$  to be a pointer to the first component of the data for the  $N_Vector v$ . The assignment  $NV_DATA_S(v) = v_{data}$  sets the component array of v to be  $v_{data}$  by storing the pointer  $v_{data}$ .

The assignment  $v_len = NV_LENGTH_S(v)$  sets  $v_len$  to be the length of v. On the other hand, the call  $NV_LENGTH_S(v) = len_v$  sets the length of v to be  $len_v$ .

Implementation:

```
#define NV_OWN_DATA_S(v) ( NV_CONTENT_S(v)->own_data )
#define NV_DATA_S(v) ( NV_CONTENT_S(v)->data )
#define NV_LENGTH_S(v) ( NV_CONTENT_S(v)->length )
```

### • NV\_Ith\_S

This macro gives access to the individual components of the data array of an N\_Vector.

The assignment  $r = NV_{i,i}$  sets r to be the value of the i-th component of v. The assignment  $NV_{i,i} = r$  sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_S(v,i) ( NV_DATA_S(v)[i] )
```

The NVECTOR\_SERIAL module defines serial implementations of all vector operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix \_Serial (e.g. N\_VDestroy\_Serial). The module NVECTOR\_SERIAL provides the following additional user-callable routines:

### • N\_VNew\_Serial

This function creates and allocates memory for a serial  $N\_Vector$ . Its only argument is the vector length.

N\_Vector N\_VNew\_Serial(sunindextype vec\_length);

### • N\_VNewEmpty\_Serial

This function creates a new serial N\_Vector with an empty (NULL) data array.

N\_Vector N\_VNewEmpty\_Serial(sunindextype vec\_length);

### • N\_VMake\_Serial

This function creates and allocates memory for a serial vector with user-provided data array.

(This function does *not* allocate memory for v\_data itself.)

```
N_Vector N_VMake_Serial(sunindextype vec_length, realtype *v_data);
```

### • N\_VCloneVectorArray\_Serial

This function creates (by cloning) an array of count serial vectors.

```
N_Vector *N_VCloneVectorArray_Serial(int count, N_Vector w);
```

### • N\_VCloneVectorArrayEmpty\_Serial

This function creates (by cloning) an array of count serial vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_Serial(int count, N_Vector w);
```

### • N\_VDestroyVectorArray\_Serial

This function frees memory allocated for the array of count variables of type N\_Vector created with N\_VCloneVectorArray\_Serial or with N\_VCloneVectorArrayEmpty\_Serial.

```
void N_VDestroyVectorArray_Serial(N_Vector *vs, int count);
```

• N\_VGetLength\_Serial

```
This function returns the number of vector elements. sunindextype N_VGetLength_Serial(N_Vector v);
```

• N\_VPrint\_Serial

This function prints the content of a serial vector to stdout.

```
void N_VPrint_Serial(N_Vector v);
```

• N\_VPrintFile\_Serial

```
This function prints the content of a serial vector to outfile. void N_VPrintFile_Serial(N_Vector v, FILE *outfile);
```

### Notes

• When looping over the components of an N\_Vector v, it is more efficient to first obtain the component array via v\_data = NV\_DATA\_S(v) and then access v\_data[i] within the loop than it is to use NV\_Ith\_S(v,i) within the loop.

• N\_VNewEmpty\_Serial, N\_VMake\_Serial, and N\_VCloneVectorArrayEmpty\_Serial set the field  $own\_data = SUNFALSE$ . N\_VDestroy\_Serial and N\_VDestroyVectorArray\_Serial will not attempt to free the pointer data for any N\_Vector with  $own\_data$  set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.

• To maximize efficiency, vector operations in the NVECTOR\_SERIAL implementation that have more than one N\_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR\_SERIAL module also includes a Fortran-callable function FNVINITS(code, NEQ, IER), to initialize this NVECTOR\_SERIAL module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); and IER is an error return flag equal 0 for success and -1 for failure.

# 7.2 The NVECTOR\_PARALLEL implementation

The NVECTOR\_PARALLEL implementation of the NVECTOR module provided with SUNDIALS is based on MPI. It defines the *content* field of N\_Vector to be a structure containing the global and local lengths of the vector, a pointer to the beginning of a contiguous local data array, an MPI communicator, and a boolean flag own\_data indicating ownership of the data array data.

```
struct _N_VectorContent_Parallel {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_data;
   realtype *data;
   MPI_Comm comm;
};
```

The header file to include when using this module is nvector\_parallel.h. The installed module library to link to is libsundials\_nvecparallel.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of a NVECTOR\_PARALLEL vector. The suffix \_P in the names denotes the distributed memory parallel version.

### NV\_CONTENT\_P

This macro gives access to the contents of the parallel vector N\_Vector.

The assignment v\_cont = NV\_CONTENT\_P(v) sets v\_cont to be a pointer to the N\_Vector content structure of type struct \_N\_VectorContent\_Parallel.

Implementation:

```
#define NV_CONTENT_P(v) ( (N_VectorContent_Parallel)(v->content) )
```

### • NV\_OWN\_DATA\_P, NV\_DATA\_P, NV\_LOCLENGTH\_P, NV\_GLOBLENGTH\_P

These macros give individual access to the parts of the content of a parallel N\_Vector.

The assignment  $v_{data} = NV_DATA_P(v)$  sets  $v_{data}$  to be a pointer to the first component of the local data for the  $N_Vector v$ . The assignment  $NV_DATA_P(v) = v_{data}$  sets the component array of v to be  $v_{data}$  by storing the pointer  $v_{data}$ .

The assignment v\_llen = NV\_LOCLENGTH\_P(v) sets v\_llen to be the length of the local part of v. The call NV\_LENGTH\_P(v) = llen\_v sets the local length of v to be llen\_v.

The assignment  $v_glen = NV_GLOBLENGTH_P(v)$  sets  $v_glen$  to be the global length of the vector v. The call  $NV_GLOBLENGTH_P(v) = glen_v$  sets the global length of v to be  $glen_v$ .

Implementation:

```
#define NV_OWN_DATA_P(v) ( NV_CONTENT_P(v)->own_data )
#define NV_DATA_P(v) ( NV_CONTENT_P(v)->data )
#define NV_LOCLENGTH_P(v) ( NV_CONTENT_P(v)->local_length )
#define NV_GLOBLENGTH_P(v) ( NV_CONTENT_P(v)->global_length )
```

### • NV COMM P

This macro provides access to the MPI communicator used by the NVECTOR\_PARALLEL vectors. Implementation:

```
#define NV_COMM_P(v) ( NV_CONTENT_P(v)->comm )
```

### • NV\_Ith\_P

This macro gives access to the individual components of the local data array of an N-Vector.

The assignment  $r = NV_Ith_P(v,i)$  sets r to be the value of the i-th component of the local part of v. The assignment  $NV_Ith_P(v,i) = r$  sets the value of the i-th component of the local part of v to be r.

Here i ranges from 0 to n-1, where n is the local length.

Implementation:

```
#define NV_Ith_P(v,i) ( NV_DATA_P(v)[i] )
```

The NVECTOR\_PARALLEL module defines parallel implementations of all vector operations listed in Table 7.2 Their names are obtained from those in Table 7.2 by appending the suffix \_Parallel (e.g. N\_VDestroy\_Parallel). The module NVECTOR\_PARALLEL provides the following additional user-callable routines:

### • N\_VNew\_Parallel

This function creates and allocates memory for a parallel vector.

### • N\_VNewEmpty\_Parallel

This function creates a new parallel N\_Vector with an empty (NULL) data array.

### • N\_VMake\_Parallel

This function creates and allocates memory for a parallel vector with user-provided data array. (This function does *not* allocate memory for v\_data itself.)

### • N\_VCloneVectorArray\_Parallel

This function creates (by cloning) an array of count parallel vectors.

```
N_Vector *N_VCloneVectorArray_Parallel(int count, N_Vector w);
```

### • N\_VCloneVectorArrayEmpty\_Parallel

This function creates (by cloning) an array of count parallel vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_Parallel(int count, N_Vector w);
```

### • N\_VDestroyVectorArray\_Parallel

This function frees memory allocated for the array of count variables of type N\_Vector created with N\_VCloneVectorArray\_Parallel or with N\_VCloneVectorArrayEmpty\_Parallel.

```
void N_VDestroyVectorArray_Parallel(N_Vector *vs, int count);
```

### • N\_VGetLength\_Parallel

This function returns the number of vector elements (global vector length). sunindextype N\_VGetLength\_Parallel(N\_Vector v);

### • N\_VGetLocalLength\_Parallel

This function returns the local vector length.

```
sunindextype N_VGetLocalLength_Parallel(N_Vector v);
```

### • N\_VPrint\_Parallel

This function prints the local content of a parallel vector to stdout. void N\_VPrint\_Parallel(N\_Vector v);

### • N\_VPrintFile\_Parallel

This function prints the local content of a parallel vector to outfile.

```
void N_VPrintFile_Parallel(N_Vector v, FILE *outfile);
```

### Notes

• When looping over the components of an N\_Vector v, it is more efficient to first obtain the local component array via v\_data = NV\_DATA\_P(v) and then access v\_data[i] within the loop than it is to use NV\_Ith\_P(v,i) within the loop.

- N\_VNewEmpty\_Parallel, N\_VMake\_Parallel, and N\_VCloneVectorArrayEmpty\_Parallel set the field own\_data = SUNFALSE. N\_VDestroy\_Parallel and N\_VDestroyVectorArray\_Parallel will not attempt to free the pointer data for any N\_Vector with own\_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.
- To maximize efficiency, vector operations in the NVECTOR\_PARALLEL implementation that have more than one N\_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR\_PARALLEL module also includes a Fortran-callable function FNVINITP(COMM, code, NLOCAL, NGLOBAL, IER), to initialize this NVECTOR\_PARALLEL module. Here COMM is the MPI communicator, code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NLOCAL and NGLOBAL are the local and global vector sizes, respectively (declared so as to match C type long int); and IER is an error return flag equal 0 for success and -1 for failure. NOTE: If the header file sundials\_config.h defines SUNDIALS\_MPI\_COMM\_F2C to be 1 (meaning the MPI implementation used to build SUNDIALS includes the MPI\_Comm\_f2c function), then COMM can be any valid MPI communicator. Otherwise, MPI\_COMM\_WORLD will be used, so just pass an integer value as a placeholder.

## 7.3 The NVECTOR\_OPENMP implementation

In situations where a user has a multi-core processing unit capable of running multiple parallel threads with shared memory, SUNDIALS provides an implementation of NVECTOR using OpenMP, called NVECTOR\_OPENMP, and an implementation using Pthreads, called NVECTOR\_PTHREADS. Testing has shown that vectors should be of length at least 100,000 before the overhead associated with creating and using the threads is made up by the parallelism in the vector calculations.

The OpenMP NVECTOR implementation provided with SUNDIALS, NVECTOR\_OPENMP, defines the content field of N\_Vector to be a structure containing the length of the vector, a pointer to the beginning of a contiguous data array, a boolean flag own\_data which specifies the ownership of data, and the number of threads. Operations on the vector are threaded using OpenMP.

```
struct _N_VectorContent_OpenMP {
   sunindextype length;
   booleantype own_data;
   realtype *data;
   int num_threads;
};
```

The header file to include when using this module is nvector\_openmp.h. The installed module library to link to is libsundials\_nvecopenmp.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR\_OPENMP vector. The suffix \_OMP in the names denotes the OpenMP version.

### NV\_CONTENT\_OMP

This routine gives access to the contents of the OpenMP vector N\_Vector.

The assignment  $v\_cont = NV\_CONTENT\_OMP(v)$  sets  $v\_cont$  to be a pointer to the OpenMP  $N\_Vector$  content structure.

Implementation:

```
#define NV_CONTENT_OMP(v) ( (N_VectorContent_OpenMP)(v->content) )
```

• NV\_OWN\_DATA\_OMP, NV\_DATA\_OMP, NV\_LENGTH\_OMP, NV\_NUM\_THREADS\_OMP

These macros give individual access to the parts of the content of a OpenMP N\_Vector.

The assignment  $v_{data} = NV_DATA_OMP(v)$  sets  $v_{data}$  to be a pointer to the first component of the data for the  $N_Vector v$ . The assignment  $NV_DATA_OMP(v) = v_{data}$  sets the component array of v to be  $v_{data}$  by storing the pointer  $v_{data}$ .

The assignment  $v_len = NV_LENGTH_OMP(v)$  sets  $v_len$  to be the length of v. On the other hand, the call  $NV_LENGTH_OMP(v) = len_v$  sets the length of v to be  $len_v$ .

The assignment v\_num\_threads = NV\_NUM\_THREADS\_OMP(v) sets v\_num\_threads to be the number of threads from v. On the other hand, the call NV\_NUM\_THREADS\_OMP(v) = num\_threads\_v sets the number of threads for v to be num\_threads\_v.

Implementation:

```
#define NV_OWN_DATA_OMP(v) ( NV_CONTENT_OMP(v)->own_data )
#define NV_DATA_OMP(v) ( NV_CONTENT_OMP(v)->data )
#define NV_LENGTH_OMP(v) ( NV_CONTENT_OMP(v)->length )
#define NV_NUM_THREADS_OMP(v) ( NV_CONTENT_OMP(v)->num_threads )
```

• NV\_Ith\_OMP

This macro gives access to the individual components of the data array of an N\_Vector.

The assignment  $r = NV_{in}(v,i)$  sets r to be the value of the i-th component of v. The assignment  $NV_{in}(v,i) = r$  sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_OMP(v,i) ( NV_DATA_OMP(v)[i] )
```

The NVECTOR\_OPENMP module defines OpenMP implementations of all vector operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix <code>\_OpenMP</code> (e.g. <code>N\_VDestroy\_OpenMP</code>). The module <code>NVECTOR\_OPENMP</code> provides the following additional user-callable routines:

### • N\_VNew\_OpenMP

This function creates and allocates memory for a OpenMP N\_Vector. Arguments are the vector length and number of threads.

```
N_Vector N_VNew_OpenMP(sunindextype vec_length, int num_threads);
```

• N\_VNewEmpty\_OpenMP

This function creates a new OpenMP N\_Vector with an empty (NULL) data array.

```
N_Vector N_VNewEmpty_OpenMP(sunindextype vec_length, int num_threads);
```

• N\_VMake\_OpenMP

This function creates and allocates memory for a OpenMP vector with user-provided data array.

(This function does *not* allocate memory for v\_data itself.)

```
N_Vector N_VMake_OpenMP(sunindextype vec_length, realtype *v_data, int num_threads);
```

• N\_VCloneVectorArray\_OpenMP

This function creates (by cloning) an array of count OpenMP vectors.

```
N_Vector *N_VCloneVectorArray_OpenMP(int count, N_Vector w);
```

• N\_VCloneVectorArrayEmpty\_OpenMP

This function creates (by cloning) an array of count OpenMP vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_OpenMP(int count, N_Vector w);
```

N\_VDestroyVectorArray\_OpenMP

This function frees memory allocated for the array of count variables of type N\_Vector created with N\_VCloneVectorArray\_OpenMP or with N\_VCloneVectorArrayEmpty\_OpenMP.

```
void N_VDestroyVectorArray_OpenMP(N_Vector *vs, int count);
```

• N\_VGetLength\_OpenMP

```
This function returns number of vector elements.
sunindextype N_VGetLength_OpenMP(N_Vector v);
```

• N\_VPrint\_OpenMP

```
This function prints the content of an OpenMP vector to stdout. void N_VPrint_OpenMP(N_Vector v);
```

• N\_VPrintFile\_OpenMP

```
This function prints the content of an OpenMP vector to outfile. void N_VPrintFile_OpenMP(N_Vector v, FILE *outfile);
```

### Notes

- When looping over the components of an N\_Vector v, it is more efficient to first obtain the component array via v\_data = NV\_DATA\_OMP(v) and then access v\_data[i] within the loop than it is to use NV\_Ith\_OMP(v,i) within the loop.
- N\_VNewEmpty\_OpenMP, N\_VMake\_OpenMP, and N\_VCloneVectorArrayEmpty\_OpenMP set the field  $own\_data = SUNFALSE$ . N\_VDestroy\_OpenMP and N\_VDestroyVectorArray\_OpenMP will not attempt to free the pointer data for any N\_Vector with  $own\_data$  set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.
- To maximize efficiency, vector operations in the NVECTOR\_OPENMP implementation that have more than one N\_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR\_OPENMP module also includes a Fortran-callable function FNVINITOMP(code, NEQ, NUMTHREADS, IER), to initialize this module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); NUMTHREADS is the number of threads; and IER is an error return flag equal 0 for success and -1 for failure.

# 7.4 The NVECTOR\_PTHREADS implementation

In situations where a user has a multi-core processing unit capable of running multiple parallel threads with shared memory, SUNDIALS provides an implementation of NVECTOR using OpenMP, called NVECTOR\_OPENMP, and an implementation using Pthreads, called NVECTOR\_PTHREADS. Testing has shown that vectors should be of length at least 100,000 before the overhead associated with creating and using the threads is made up by the parallelism in the vector calculations.

The Pthreads NVECTOR implementation provided with SUNDIALS, denoted NVECTOR\_PTHREADS, defines the *content* field of N\_Vector to be a structure containing the length of the vector, a pointer

to the beginning of a contiguous data array, a boolean flag  $own\_data$  which specifies the ownership of data, and the number of threads. Operations on the vector are threaded using POSIX threads (Pthreads).

```
struct _N_VectorContent_Pthreads {
   sunindextype length;
   booleantype own_data;
   realtype *data;
   int num_threads;
};
```

The header file to include when using this module is nvector\_pthreads.h. The installed module library to link to is libsundials\_nvecpthreads.lib where .lib is typically .so for shared libraries and .a for static libraries.

The following macros are provided to access the content of an NVECTOR\_PTHREADS vector. The suffix \_PT in the names denotes the Pthreads version.

### NV\_CONTENT\_PT

This routine gives access to the contents of the Pthreads vector N\_Vector.

The assignment  $v\_cont = NV\_CONTENT\_PT(v)$  sets  $v\_cont$  to be a pointer to the Pthreads  $N\_Vector$  content structure.

Implementation:

```
#define NV_CONTENT_PT(v) ( (N_VectorContent_Pthreads)(v->content) )
```

• NV\_OWN\_DATA\_PT, NV\_DATA\_PT, NV\_LENGTH\_PT, NV\_NUM\_THREADS\_PT

These macros give individual access to the parts of the content of a Pthreads N\_Vector.

The assignment  $v_{data} = NV_DATA_PT(v)$  sets  $v_{data}$  to be a pointer to the first component of the data for the  $N_Vector v$ . The assignment  $NV_DATA_PT(v) = v_{data}$  sets the component array of v to be  $v_{data}$  by storing the pointer  $v_{data}$ .

The assignment  $v_len = NV_LENGTH_PT(v)$  sets  $v_len$  to be the length of v. On the other hand, the call  $NV_LENGTH_PT(v) = len_v$  sets the length of v to be  $len_v$ .

The assignment v\_num\_threads = NV\_NUM\_THREADS\_PT(v) sets v\_num\_threads to be the number of threads from v. On the other hand, the call NV\_NUM\_THREADS\_PT(v) = num\_threads\_v sets the number of threads for v to be num\_threads\_v.

Implementation:

```
#define NV_OWN_DATA_PT(v) ( NV_CONTENT_PT(v)->own_data )
#define NV_DATA_PT(v) ( NV_CONTENT_PT(v)->data )
#define NV_LENGTH_PT(v) ( NV_CONTENT_PT(v)->length )
#define NV_NUM_THREADS_PT(v) ( NV_CONTENT_PT(v)->num_threads )
```

### • NV\_Ith\_PT

This macro gives access to the individual components of the data array of an N-Vector.

The assignment  $r = NV_{int}PT(v,i)$  sets r to be the value of the i-th component of v. The assignment  $NV_{int}PT(v,i) = r$  sets the value of the i-th component of v to be r.

Here i ranges from 0 to n-1 for a vector of length n.

Implementation:

```
#define NV_Ith_PT(v,i) ( NV_DATA_PT(v)[i] )
```

The NVECTOR\_PTHREADS module defines Pthreads implementations of all vector operations listed in Table 7.2. Their names are obtained from those in Table 7.2 by appending the suffix \_Pthreads (e.g. N\_VDestroy\_Pthreads). The module NVECTOR\_PTHREADS provides the following additional user-callable routines:

### • N\_VNew\_Pthreads

This function creates and allocates memory for a Pthreads N\_Vector. Arguments are the vector length and number of threads.

N\_Vector N\_VNew\_Pthreads(sunindextype vec\_length, int num\_threads);

### • N\_VNewEmpty\_Pthreads

This function creates a new Pthreads N\_Vector with an empty (NULL) data array.

N\_Vector N\_VNewEmpty\_Pthreads(sunindextype vec\_length, int num\_threads);

### • N\_VMake\_Pthreads

This function creates and allocates memory for a Pthreads vector with user-provided data array.

(This function does *not* allocate memory for v\_data itself.)

N\_Vector N\_VMake\_Pthreads(sunindextype vec\_length, realtype \*v\_data, int num\_threads);

### • N\_VCloneVectorArray\_Pthreads

This function creates (by cloning) an array of count Pthreads vectors.

N\_Vector \*N\_VCloneVectorArray\_Pthreads(int count, N\_Vector w);

### • N\_VCloneVectorArrayEmpty\_Pthreads

This function creates (by cloning) an array of count Pthreads vectors, each with an empty (NULL) data array.

N\_Vector \*N\_VCloneVectorArrayEmpty\_Pthreads(int count, N\_Vector w);

### • N\_VDestroyVectorArray\_Pthreads

This function frees memory allocated for the array of count variables of type N\_Vector created with N\_VCloneVectorArray\_Pthreads or with N\_VCloneVectorArrayEmpty\_Pthreads.

void N\_VDestroyVectorArray\_Pthreads(N\_Vector \*vs, int count);

### • N\_VGetLength\_Pthreads

This function returns the number of vector elements.

sunindextype N\_VGetLength\_Pthreads(N\_Vector v);

### • N\_VPrint\_Pthreads

This function prints the content of a Pthreads vector to stdout.

void N\_VPrint\_Pthreads(N\_Vector v);

### • N\_VPrintFile\_Pthreads

This function prints the content of a Pthreads vector to outfile.

void N\_VPrintFile\_Pthreads(N\_Vector v, FILE \*outfile);

### Notes

- When looping over the components of an N\_Vector v, it is more efficient to first obtain the component array via v\_data = NV\_DATA\_PT(v) and then access v\_data[i] within the loop than it is to use NV\_Ith\_PT(v,i) within the loop.
- N\_VNewEmpty\_Pthreads, N\_VMake\_Pthreads, and N\_VCloneVectorArrayEmpty\_Pthreads set the field own\_data = SUNFALSE. N\_VDestroy\_Pthreads and N\_VDestroyVectorArray\_Pthreads will not attempt to free the pointer data for any N\_Vector with own\_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the data pointer.

⚠

• To maximize efficiency, vector operations in the NVECTOR\_PTHREADS implementation that have more than one N\_Vector argument do not check for consistent internal representation of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

For solvers that include a Fortran interface module, the NVECTOR\_PTHREADS module also includes a Fortran-callable function FNVINITPTS(code, NEQ, NUMTHREADS, IER), to initialize this module. Here code is an input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); NEQ is the problem size (declared so as to match C type long int); NUMTHREADS is the number of threads; and IER is an error return flag equal 0 for success and -1 for failure.

## 7.5 The NVECTOR\_PARHYP implementation

The NVECTOR\_PARHYP implementation of the NVECTOR module provided with SUNDIALS is a wrapper around *hypre*'s ParVector class. Most of the vector kernels simply call *hypre* vector operations. The implementation defines the *content* field of N\_Vector to be a structure containing the global and local lengths of the vector, a pointer to an object of type hypre\_ParVector, an MPI communicator, and a boolean flag *own\_parvector* indicating ownership of the *hypre* parallel vector object *x*.

```
struct _N_VectorContent_ParHyp {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_parvector;
   MPI_Comm comm;
   hypre_ParVector *x;
};
```

The header file to include when using this module is nvector\_parhyp.h. The installed module library to link to is libsundials\_nvecparhyp.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike native SUNDIALS vector types, NVECTOR\_PARHYP does not provide macros to access its member variables. Note that NVECTOR\_PARHYP requires SUNDIALS to be built with MPI support.

The NVECTOR\_PARHYP module defines implementations of all vector operations listed in Table 7.2, except for N\_VSetArrayPointer and N\_VGetArrayPointer, because accessing raw vector data is handled by low-level hypre functions. As such, this vector is not available for use with SUNDIALS Fortran interfaces. When access to raw vector data is needed, one should extract the hypre vector first, and then use hypre methods to access the data. Usage examples of NVECTOR\_PARHYP are provided in the cvAdvDiff\_non\_ph.c example program for CVODE [23] and the ark\_diurnal\_kry\_ph.c example program for ARKODE [31].

The names of parhyp methods are obtained from those in Table 7.2 by appending the suffix \_Parhyp (e.g. N\_VDestroy\_Parhyp). The module NVECTOR\_PARHYP provides the following additional user-callable routines:

### N\_VNewEmpty\_ParHyp

This function creates a new parhyp N\_Vector with the pointer to the hypre vector set to NULL.

### • N\_VMake\_ParHyp

This function creates an N\_Vector wrapper around an existing hypre parallel vector. It does not allocate memory for x itself.

```
N_Vector N_VMake_ParHyp(hypre_ParVector *x);
```

#### • N\_VGetVector\_ParHyp

This function returns a pointer to the underlying hypre vector.

```
hypre_ParVector *N_VGetVector_ParHyp(N_Vector v);
```

#### • N\_VCloneVectorArray\_ParHyp

This function creates (by cloning) an array of count parallel vectors.

```
N_Vector *N_VCloneVectorArray_ParHyp(int count, N_Vector w);
```

#### • N\_VCloneVectorArrayEmpty\_ParHyp

This function creates (by cloning) an array of count parallel vectors, each with an empty (NULL) data array.

```
N_Vector *N_VCloneVectorArrayEmpty_ParHyp(int count, N_Vector w);
```

#### • N\_VDestroyVectorArray\_ParHyp

This function frees memory allocated for the array of count variables of type N\_Vector created with N\_VCloneVectorArray\_ParHyp or with N\_VCloneVectorArrayEmpty\_ParHyp.

```
void N_VDestroyVectorArray_ParHyp(N_Vector *vs, int count);
```

#### N\_VPrint\_ParHyp

This function prints the local content of a parhyp vector to stdout.

```
void N_VPrint_ParHyp(N_Vector v);
```

#### • N\_VPrintFile\_ParHyp

This function prints the local content of a parhyp vector to outfile.

```
void N_VPrintFile_ParHyp(N_Vector v, FILE *outfile);
```

#### Notes

- When there is a need to access components of an N\_Vector\_ParHyp, v, it is recommended to extract the hypre vector via x\_vec = N\_VGetVector\_ParHyp(v) and then access components using appropriate hypre functions.
- N\_VNewEmpty\_ParHyp, N\_VMake\_ParHyp, and N\_VCloneVectorArrayEmpty\_ParHyp set the field own\_parvector to SUNFALSE. N\_VDestroy\_ParHyp and N\_VDestroyVectorArray\_ParHyp will not attempt to delete an underlying hypre vector for any N\_Vector with own\_parvector set to SUNFALSE. In such a case, it is the user's responsibility to delete the underlying vector.
- To maximize efficiency, vector operations in the NVECTOR\_PARHYP implementation that have more than one N\_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

# 7.6 The NVECTOR\_PETSC implementation

The NVECTOR\_PETSC module is an NVECTOR wrapper around the PETSc vector. It defines the *content* field of a N\_Vector to be a structure containing the global and local lengths of the vector, a pointer to the PETSc vector, an MPI communicator, and a boolean flag own\_data indicating ownership of the wrapped PETSc vector.

```
struct _N_VectorContent_Petsc {
   sunindextype local_length;
   sunindextype global_length;
   booleantype own_data;
   Vec *pvec;
   MPI_Comm comm;
};
```

The header file to include when using this module is nvector\_petsc.h. The installed module library to link to is libsundials\_nvecpetsc.lib where .lib is typically .so for shared libraries and .a for static libraries.

Unlike native SUNDIALS vector types, NVECTOR\_PETSC does not provide macros to access its member variables. Note that NVECTOR\_PETSC requires SUNDIALS to be built with MPI support.

The NVECTOR\_PETSC module defines implementations of all vector operations listed in Table 7.2, except for N\_VGetArrayPointer and N\_VSetArrayPointer. As such, this vector cannot be used with SUNDIALS Fortran interfaces. When access to raw vector data is needed, it is recommended to extract the PETSC vector first, and then use PETSC methods to access the data. Usage examples of NVECTOR\_PETSC are provided in example programs for IDA [22].

The names of vector operations are obtained from those in Table 7.2 by appending the suffix \_Petsc (e.g. N\_VDestroy\_Petsc). The module NVECTOR\_PETSC provides the following additional user-callable routines:

#### • N\_VNewEmpty\_Petsc

This function creates a new NVECTOR wrapper with the pointer to the wrapped PETSc vector set to (NULL). It is used by the N\_VMake\_Petsc and N\_VClone\_Petsc implementations.

#### • N\_VMake\_Petsc

This function creates and allocates memory for an NVECTOR\_PETSC wrapper around a user-provided PETSc vector. It does not allocate memory for the vector pvec itself.

```
N_Vector N_VMake_Petsc(Vec *pvec);
```

#### • N\_VGetVector\_Petsc

This function returns a pointer to the underlying PETSc vector.

```
Vec *N_VGetVector_Petsc(N_Vector v);
```

#### • N\_VCloneVectorArray\_Petsc

This function creates (by cloning) an array of count NVECTOR\_PETSC vectors.

```
N_Vector *N_VCloneVectorArray_Petsc(int count, N_Vector w);
```

#### • N\_VCloneVectorArrayEmpty\_Petsc

This function creates (by cloning) an array of count NVECTOR\_PETSC vectors, each with pointers to PETSC vectors set to (NULL).

```
N_Vector *N_VCloneVectorArrayEmpty_Petsc(int count, N_Vector w);
```

• N\_VDestroyVectorArray\_Petsc

This function frees memory allocated for the array of count variables of type  $N_V$  created with  $N_V$ CloneVectorArray\_Petsc or with  $N_V$ CloneVectorArrayEmpty\_Petsc.

```
void N_VDestroyVectorArray_Petsc(N_Vector *vs, int count);
```

• N\_VPrint\_Petsc

```
This function prints the global content of a wrapped PETSc vector to {\tt stdout}.
```

```
void N_VPrint_Petsc(N_Vector v);
```

• N\_VPrintFile\_Petsc

This function prints the global content of a wrapped PETSc vector to fname.

```
void N_VPrintFile_Petsc(N_Vector v, const char fname[]);
```

#### Notes

- When there is a need to access components of an N\_Vector\_Petsc, v, it is recommeded to extract the PETSc vector via x\_vec = N\_VGetVector\_Petsc(v) and then access components using appropriate PETSc functions.
- The functions N\_VNewEmpty\_Petsc, N\_VMake\_Petsc, and N\_VCloneVectorArrayEmpty\_Petsc set the field own\_data to SUNFALSE. N\_VDestroy\_Petsc and N\_VDestroyVectorArray\_Petsc will not attempt to free the pointer pvec for any N\_Vector with own\_data set to SUNFALSE. In such a case, it is the user's responsibility to deallocate the pvec pointer.
- To maximize efficiency, vector operations in the NVECTOR\_PETSC implementation that have more than one N\_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

# 7.7 The NVECTOR\_CUDA implementation

The NVECTOR\_CUDA module is an experimental NVECTOR implementation in the CUDA language. The module allows for SUNDIALS vector kernels to run on GPU devices. It is intended for users who are already familiar with CUDA and GPU programming. Building this vector module requires a CUDA compiler and, by extension, a C++ compiler. The class Vector in namespace suncudavec manages vector data layout:

```
template <class T, class I>
class Vector {
    I size_;
    I mem_size_;
    T* h_vec_;
    T* d_vec_;
    ThreadPartitioning<T, I>* partStream_;
    ThreadPartitioning<T, I>* partReduce_;
    bool ownPartitioning_;
    ...
};
```

The class members are vector size (length), size of the vector data memory block, pointers to vector data on the host and the device, pointers to ThreadPartitioning implementations that handle thread partitioning for streaming and reduction vector kernels, and a boolean flag that signals if the vector owns the thread partitioning. The class Vector inherits from the empty structure

```
struct _N_VectorContent_Cuda {
};
```

to interface the C++ class with the NVECTOR C code. When instantiated, the class Vector will allocate memory on both the host and the device. Due to the rapid progress of CUDA development, we expect that the suncudavec::Vector class will change frequently in future SUNDIALS releases. The code is structured so that it can tolerate significant changes in the suncudavec::Vector class without requiring changes to the user API.

The NVECTOR\_CUDA module can be utilized for single-node parallelism or in a distributed context with MPI. The header file to include when using this module for single-node parallelism is nvector\_cuda.h. The header file to include when using this module in the distributed case is nvector\_mpicuda.h. Note that only the NVECTOR\_CUDA constructor signature differs between the two header files. The installed module libraries to link to are libsundials\_nveccuda.lib in the single-node case, or libsundials\_nvecmpicuda.lib in the distributed case. Only one one of these libraries may be linked to when creating an executable or library. SUNDIALS must be built with MPI support if the distributed library is desired. The extension, .lib, is typically .so for shared libraries and .a for static libraries.

Unlike other native SUNDIALS vector types, NVECTOR\_CUDA does not provide macros to access its member variables. Instead, user should use the accessor functions in the namespace suncudavec.

#### • getDevData(N\_Vector v)

This function takes an N\_Vector as an argument and returns a raw pointer to the vector data on the device (GPU). It is the user's responsibility to ensure that the vector argument is of the correct N\_Vector type.

#### • getHostData(N\_Vector v)

This function takes a N\_Vector as an argument and returns a raw pointer to the vector data on the host (CPU memory). It is the user's responsibility to ensure that the vector argument is of the correct N\_Vector type.

• getSize(N\_Vector v)

Returns the vector's local length.

• getGlobalSize(N\_Vector v)

Returns the vector's global length.

• getMPIComm(N\_Vector v)

Takes a N\_Vector as an argument and returns a sundials communicator of type SUNDIALS\_Comm.

The NVECTOR\_CUDA module defines implementations of all vector operations listed in Table 7.2, except for N\_VGetArrayPointer and N\_VSetArrayPointer. As such, this vector cannot be used with the SUNDIALS Fortran interfaces, nor with the SUNDIALS direct solvers and preconditioners. Instead, the NVECTOR\_CUDA module provides separate functions to access data on the host and on the device. It also provides methods for copying from the host to the device and vice versa. Usage examples of NVECTOR\_CUDA are provided in some example programs for CVODE [23].

The names of vector operations are obtained from those in Table 7.2 by appending the suffix \_Cuda (e.g. N\_VDestroy\_Cuda). The module NVECTOR\_CUDA provides the following additional user-callable routines:

#### • N\_VNew\_Cuda

Note: this function signature is defined in the header nvector\_mpicuda.h and should be used when using this module in a distributed context. This function creates and allocates memory for a CUDA N\_Vector. The memory is allocated on both host and device. Its arguments are local and global vector lengths, as well as the MPI communicator. Use this constructor with the libsundials\_nvecmpicuda.lib library.

#### • N\_VNew\_Cuda

Note: this function signature is defined in the header nvector\_cuda.h and should be used when using this module for single-node parallelism. This function creates and allocates memory for a CUDA N\_Vector on a single node. The memory is allocated on both host and device. Its only argument is vector length. Use this constructor with the libsundials\_nveccuda.lib library.

N\_Vector N\_VNew\_Cuda(sunindextype length);

#### • N\_VNewEmpty\_Cuda

This function creates a new NVECTOR wrapper with the pointer to the wrapped CUDA vector set to (NULL). It is used by the N\_VNew\_Cuda, N\_VMake\_Cuda, and N\_VClone\_Cuda implementations.

N\_Vector N\_VNewEmpty\_Cuda(sunindextype vec\_length);

#### • N\_VMake\_Cuda

This function creates and allocates memory for an NVECTOR\_CUDA wrapper around a user-provided suncudavec::Vector class. Its only argument is of type N\_VectorContent\_Cuda, which is the pointer to the class.

N\_Vector N\_VMake\_Cuda(N\_VectorContent\_Cuda c);

#### • N\_VGetLength\_Cuda

This function returns the length of the vector.

```
sunindextype N_VGetLength_Cuda(N_Vector v);
```

#### • N\_VGetHostArrayPointer\_Cuda

This function returns a pointer to the vector data on the host.

```
realtype *N_VGetHostArrayPointer_Cuda(N_Vector v);
```

#### • N\_VGetDeviceArrayPointer\_Cuda

This function returns a pointer to the vector data on the device.

```
realtype *N_VGetDeviceArrayPointer_Cuda(N_Vector v);
```

#### • N\_VCopyToDevice\_Cuda

This function copies host vector data to the device.

```
realtype *N_VCopyToDevice_Cuda(N_Vector v);
```

#### • N\_VCopyFromDevice\_Cuda

This function copies vector data from the device to the host.

```
realtype *N_VCopyFromDevice_Cuda(N_Vector v);
```

#### • N\_VPrint\_Cuda

This function prints the content of a CUDA vector to stdout. void N\_VPrint\_Cuda(N\_Vector v);

• N\_VPrintFile\_Cuda

This function prints the content of a CUDA vector to outfile. void N\_VPrintFile\_Cuda(N\_Vector v, FILE \*outfile);

#### Notes

• When there is a need to access components of an N\_Vector\_Cuda, v, it is recommeded to use functions N\_VGetDeviceArrayPointer\_Cuda or N\_VGetHostArrayPointer\_Cuda.

• To maximize efficiency, vector operations in the NVECTOR\_CUDA implementation that have more than one N\_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

### 7.8 The NVECTOR\_RAJA implementation

The NVECTOR\_RAJA module is an experimental NVECTOR implementation using the RAJA hardware abstraction layer. In this implementation, RAJA allows for SUNDIALS vector kernels to run on GPU devices. The module is intended for users who are already familiar with RAJA and GPU programming. Building this vector module requires a C++11 compliant compiler and a CUDA software development toolkit. Besides the CUDA backend, RAJA has other backends such as serial, OpenMP, and OpenAC. These backends are not used in this SUNDIALS release. Class Vector in namespace sunrajavec manages the vector data layout:

```
template <class T, class I>
class Vector {
   I size_;
   I mem_size_;
   T* h_vec_;
   T* d_vec_;
   ...
};
```

The class members are: vector size (length), size of the vector data memory block, and pointers to vector data on the host and on the device. The class Vector inherits from an empty structure

```
struct _N_VectorContent_Raja {
};
```

to interface the C++ class with the NVECTOR C code. When instantiated, the class Vector will allocate memory on both the host and the device. Due to the rapid progress of RAJA development, we expect that the sunrajavec::Vector class will change frequently in future SUNDIALS releases. The code is structured so that it can tolerate significant changes in the sunrajavec::Vector class without requiring changes to the user API.

The NVECTOR\_RAJA module can be utilized for single-node parallelism or in a distributed context with MPI. The header file to include when using this module for single-node parallelism is nvector\_raja.h. The header file to include when using this module in the distributed case is nvector\_mpiraja.h. Note that only the NVECTOR\_RAJA constructor signature differs between the two header files. The installed module libraries to link to are libsundials\_nvecraja.lib in the single-node case, or libsundials\_nvecmpicudaraja.lib in the distributed case. Only one one of these libraries may be linked to when creating an executable or library. SUNDIALS must be built with MPI support if the distributed library is desired. The extension, .lib, is typically .so for shared libraries and .a for static libraries.

Unlike other native SUNDIALS vector types, NVECTOR\_RAJA does not provide macros to access its member variables. Instead, user should use the accessor functions in the namespace sunrajavec.

#### • getDevData(N\_Vector v)

This function takes a N\_Vector as an argument and returns a raw pointer to the vector data on the device (GPU). It is the user's responsibility to ensure that the vector argument is of the correct N\_Vector type.

#### • getHostData(N\_Vector v)

This function takes a N\_Vector as an argument and returns a raw pointer to the vector data on the host (CPU memory). It is the user's responsibility to ensure that the vector argument is of the correct N\_Vector type.

• getSize(N\_Vector v)

Returns the vector's local length.

• getGlobalSize(N\_Vector v) Returns the vector's global length.

• getMPIComm(N\_Vector v)

Takes a N\_Vector as an argument and returns a sundials communicator of type SUNDIALS\_Comm.

The NVECTOR\_RAJA module defines the implementations of all vector operations listed in Table 7.2, except for N\_VGetArrayPointer and N\_VSetArrayPointer. As such, this vector cannot be used with the SUNDIALS Fortran interfaces, nor with the SUNDIALS direct solvers and preconditioners. The NVECTOR\_RAJA module provides separate functions to access data on the host and on the device. It also provides methods for copying data from the host to the device and vice versa. Usage examples of NVECTOR\_RAJA are provided in some example programs for CVODE [23].

The names of vector operations are obtained from those in Table 7.2 by appending the suffix Raja (e.g. N\_VDestroy\_Raja). The module NVECTOR\_RAJA provides the following additional user-callable routines:

#### • N\_VNew\_Raja

Note: this function signature is defined in the header nvector\_mpiraja.h and should be used when using this module in a distributed context. This function creates and allocates memory for a RAJA N\_Vector. The memory is allocated on both host and device. Its arguments are local and global vector lengths, as well as the MPI communicator. Use this constructor with the libsundials\_nvecmpicudaraja.lib library.

#### • N\_VNew\_Raja

Note: this function signature is defined in the header nvector\_raja.h and should be used when using this module for single-node parallelism. This function creates and allocates memory for a RAJA N\_Vector on a single node. The memory is allocated on both host and device. Its only argument is vector length. Use this constructor with the libsundials\_nveccudaraja.lib library.

N\_Vector N\_VNew\_Raja(sunindextype length);

#### • N\_VNewEmpty\_Raja

This function creates a new NVECTOR wrapper with the pointer to the wrapped RAJA vector set to (NULL). It is used by the N\_VNew\_Raja, N\_VMake\_Raja, and N\_VClone\_Raja implementations.

N\_Vector N\_VNewEmpty\_Raja(sunindextype vec\_length);

#### • N\_VMake\_Raja

This function creates and allocates memory for an NVECTOR\_RAJA wrapper around a user-provided sunrajavec::Vector class. Its only argument is of type N\_VectorContent\_Raja, which is the pointer to the class.

```
N_Vector N_VMake_Raja(N_VectorContent_Raja c);
• N_VGetLength_Raja
```

This function returns the length of the vector. sunindextype N\_VGetLength\_Raja(N\_Vector v);

• N\_VGetHostArrayPointer\_Raja

This function returns a pointer to the vector data on the host. realtype \*N\_VGetHostArrayPointer\_Raja(N\_Vector v);

 $\bullet \ {\tt N\_VGetDeviceArrayPointer\_Raja}$ 

This function returns a pointer to the vector data on the device. realtype \*N\_VGetDeviceArrayPointer\_Raja(N\_Vector v);

• N\_VCopyToDevice\_Raja

This function copies host vector data to the device. realtype \*N\_VCopyToDevice\_Raja(N\_Vector v);

• N\_VCopyFromDevice\_Raja

This function copies vector data from the device to the host.
realtype \*N\_VCopyFromDevice\_Raja(N\_Vector v);

• N\_VPrint\_Raja

This function prints the content of a RAJA vector to stdout. void N\_VPrint\_Raja(N\_Vector v);

• N\_VPrintFile\_Raja

This function prints the content of a RAJA vector to outfile. void N\_VPrintFile\_Raja(N\_Vector v, FILE \*outfile);

#### Notes

- When there is a need to access components of an N\_Vector\_Raja, v, it is recommeded to use functions N\_VGetDeviceArrayPointer\_Raja or N\_VGetHostArrayPointer\_Raja.
- To maximize efficiency, vector operations in the NVECTOR\_RAJA implementation that have more than one N\_Vector argument do not check for consistent internal representations of these vectors. It is the user's responsibility to ensure that such routines are called with N\_Vector arguments that were all created with the same internal representations.

# 7.9 NVECTOR Examples

There are NVector examples that may be installed for the implementations provided with SUNDIALS. Each implementation makes use of the functions in test\_nvector.c. These example functions show simple usage of the NVector family of functions. The input to the examples are the vector length, number of threads (if threaded implementation), and a print timing flag.

The following is a list of the example functions in test\_nvector.c:

- Test\_N\_VClone: Creates clone of vector and checks validity of clone.
- Test\_N\_VCloneEmpty: Creates clone of empty vector and checks validity of clone.
- Test\_N\_VCloneVectorArray: Creates clone of vector array and checks validity of cloned array.

- Test\_N\_VCloneVectorArray: Creates clone of empty vector array and checks validity of cloned array.
- Test\_N\_VGetArrayPointer: Get array pointer.
- Test\_N\_VSetArrayPointer: Allocate new vector, set pointer to new vector array, and check values.
- Test\_N\_VLinearSum Case 1a: Test y = x + y
- Test\_N\_VLinearSum Case 1b: Test y = -x + y
- Test\_N\_VLinearSum Case 1c: Test y = ax + y
- Test\_N\_VLinearSum Case 2a: Test x = x + y
- Test\_N\_VLinearSum Case 2b: Test x = x y
- Test\_N\_VLinearSum Case 2c: Test x = x + by
- Test\_N\_VLinearSum Case 3: Test z = x + y
- Test\_N\_VLinearSum Case 4a: Test z = x y
- Test\_N\_VLinearSum Case 4b: Test z = -x + y
- Test\_N\_VLinearSum Case 5a: Test z = x + by
- Test\_N\_VLinearSum Case 5b: Test z = ax + y

- Test\_N\_VLinearSum Case 7: Test z = a(x + y)
- Test\_N\_VLinearSum Case 8: Test z = a(x y)
- Test\_N\_VLinearSum Case 9: Test z = ax + by
- Test\_N\_VConst: Fill vector with constant and check result.
- Test\_N\_VProd: Test vector multiply: z = x \* y
- Test\_N\_VDiv: Test vector division: z = x / y
- Test\_N\_VScale: Case 1: scale: x = cx
- Test\_N\_VScale: Case 2: copy: z = x
- Test\_N\_VScale: Case 3: negate: z = -x
- Test\_N\_VScale: Case 4: combination: z = cx
- Test\_N\_VAbs: Create absolute value of vector.
- Test\_N\_VAddConst: add constant vector: z = c + x
- Test\_N\_VDotProd: Calculate dot product of two vectors.
- Test\_N\_VMaxNorm: Create vector with known values, find and validate max norm.
- Test\_N\_VWrmsNorm: Create vector of known values, find and validate weighted root mean square.

- Test\_N\_VWrmsNormMask: Case 1: Create vector of known values, find and validate weighted root mean square using all elements.
- Test\_N\_VWrmsNormMask: Case 2: Create vector of known values, find and validate weighted root mean square using no elements.
- Test\_N\_VMin: Create vector, find and validate the min.
- Test\_N\_VWL2Norm: Create vector, find and validate the weighted Euclidean L2 norm.
- Test\_N\_VL1Norm: Create vector, find and validate the L1 norm.
- Test\_N\_VCompare: Compare vector with constant returning and validating comparison vector.
- Test\_N\_VInvTest: Test z[i] = 1 / x[i]
- Test\_N\_VConstrMask: Test mask of vector x with vector c.
- Test\_N\_VMinQuotient: Fill two vectors with known values. Calculate and validate minimum quotient.

# 7.10 NVECTOR functions used by CVODES

In Table 7.3 below, we list the vector functions in the NVECTOR module used within the CVODES package. The table also shows, for each function, which of the code modules uses the function. The CVODES column shows function usage within the main integrator module, while the remaining columns show function usage within each of the CVODES linear solver interfaces, the CVBANDPRE and CVBBDPRE preconditioner modules, and the CVODES adjoint sensitivity module (denoted here by CVODEA). Here CVDLS stands for the direct linear solver interface in CVODES; CVSPILS stands for the scaled, preconditioned, iterative linear solver interface in CVODES.

At this point, we should emphasize that the CVODES user does not need to know anything about the usage of vector functions by the CVODES code modules in order to use CVODES. The information is presented as an implementation detail for the interested reader.

The vector functions listed in Table 7.2 that are *not* used by CVODES are: N\_VWL2Norm, N\_VL1Norm, N\_VWrmsNormMask, and N\_VCloneEmpty. Therefore, a user-supplied NVECTOR module for CVODES could omit these kernels. The functions N\_MinQuotient, N\_VConstrMask, and N\_VCompare are only used when constraint checking is enabled and may be omitted if this feature is not used.

Table 7.3: List of vector functions usage by CVODES code modules

	CVODES	CVDLS	CVDIAG	CVSPILS	CVBANDPRE	CVBBDPRE	CVODEA
N_VGetVectorID							
$N_{-}VClone$	<b>√</b>		<b>√</b>	<b>√</b>			<b>√</b>

# Chapter 8

# Description of the SUNMatrix module

For problems that involve direct methods for solving linear systems, the SUNDIALS solvers not only operate on generic vectors, but also on generic matrices (of type SUNMatrix), through a set of operations defined by the particular SUNMATRIX implementation. Users can provide their own specific implementation of the SUNMATRIX module, particularly in cases where they provide their own NVECTOR and/or linear solver modules, and require matrices that are compatible with those implementations. Alternately, we provide three SUNMATRIX implementations: dense, banded, and sparse. The generic operations are described below, and descriptions of the implementations provided with SUNDIALS follow.

The generic SUNMatrix type has been modeled after the object-oriented style of the generic N\_Vector type. Specifically, a generic SUNMatrix is a pointer to a structure that has an implementation-dependent *content* field containing the description and actual data of the matrix, and an *ops* field pointing to a structure with generic matrix operations. The type SUNMatrix is defined as

```
typedef struct _generic_SUNMatrix *SUNMatrix;
struct _generic_SUNMatrix {
    void *content;
    struct _generic_SUNMatrix_Ops *ops;
};
```

The \_generic\_SUNMatrix\_Ops structure is essentially a list of pointers to the various actual matrix operations, and is defined as

```
struct _generic_SUNMatrix_Ops {
  SUNMatrix_ID (*getid)(SUNMatrix);
  SUNMatrix
               (*clone)(SUNMatrix);
  void
               (*destroy)(SUNMatrix);
  int
               (*zero)(SUNMatrix);
  int
               (*copy)(SUNMatrix, SUNMatrix);
               (*scaleadd)(realtype, SUNMatrix, SUNMatrix);
  int
  int
               (*scaleaddi)(realtype, SUNMatrix);
  int
               (*matvec)(SUNMatrix, N_Vector, N_Vector);
  int
               (*space)(SUNMatrix, long int*, long int*);
};
```

The generic SUNMATRIX module defines and implements the matrix operations acting on SUNMatrix objects. These routines are nothing but wrappers for the matrix operations defined by a particular SUNMATRIX implementation, which are accessed through the *ops* field of the SUNMatrix structure. To

Matrix ID	Matrix type	ID Value
SUNMATRIX_DENSE	Dense $M \times N$ matrix	0
SUNMATRIX_BAND	Band $M \times M$ matrix	1
SUNMATRIX_SPARSE	Sparse (CSR or CSC) $M \times N$ matrix	2
SUNMATRIX_CUSTOM	User-provided custom matrix	3

Table 8.1: Identifiers associated with matrix kernels supplied with SUNDIALS.

illustrate this point we show below the implementation of a typical matrix operation from the generic SUNMATRIX module, namely SUNMatZero, which sets all values of a matrix A to zero, returning a flag denoting a successful/failed operation:

```
int SUNMatZero(SUNMatrix A)
{
  return((int) A->ops->zero(A));
}
```

Table 8.2 contains a complete list of all matrix operations defined by the generic Sunmatrix module. A particular implementation of the Sunmatrix module must:

- Specify the *content* field of the SUNMatrix object.
- Define and implement a minimal subset of the matrix operations. See the documentation for each SUNDIALS solver to determine which SUNMATRIX operations they require.
  - Note that the names of these routines should be unique to that implementation in order to permit using more than one SUNMATRIX module (each with different SUNMatrix internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free a SUNMatrix with the new *content* field and with *ops* pointing to the new matrix operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined SUNMatrix (e.g., a routine to print the content for debugging purposes).
- Optionally, provide accessor macros or functions as needed for that particular implementation to access different parts of the *content* field of the newly defined SUNMatrix.

Each SUNMATRIX implementation included in SUNDIALS has a unique identifier specified in enumeration and shown in Table 8.1. It is recommended that a user-supplied SUNMATRIX implementation use the SUNMATRIX\_CUSTOM identifier.

Name	Usage and Description
SUNMatGetID	id = SUNMatGetID(A); Returns the type identifier for the matrix A. It is used to determine the matrix implementation type (e.g. dense, banded, sparse,) from the abstract SUNMatrix interface. This is used to assess compatibility with SUNDIALS-provided linear solver implementations. Returned values are given in the Table 8.1.
	continued on next page

Table 8.2: Description of the SUNMatrix operations

Name	Usage and Description
SUNMatClone	B = SUNMatClone(A); Creates a new SUNMatrix of the same type as an existing matrix A and sets the <i>ops</i> field. It does not copy the matrix, but rather allocates storage for the new matrix.
SUNMatDestroy	SUNMatDestroy(A); Destroys the SUNMatrix A and frees memory allocated for its internal data.
SUNMatSpace	ier = SUNMatSpace(A, &lrw, &liw); Returns the storage requirements for the matrix A. lrw is a long int containing the number of realtype words and liw is a long int containing the number of integer words. The return value is an integer flag denoting success/failure of the operation.  This function is advisory only, for use in determining a user's total space requirements; it could be a dummy function in a user-supplied SUNMATRIX module if that information is not of interest.
SUNMatZero	ier = SUNMatZero(A); Performs the operation $A_{ij} = 0$ for all entries of the matrix $A$ . The return value is an integer flag denoting success/failure of the operation.
SUNMatCopy	ier = SUNMatCopy(A,B); Performs the operation $B_{ij} = A_{i,j}$ for all entries of the matrices $A$ and $B$ . The return value is an integer flag denoting success/failure of the operation.
SUNMatScaleAdd	ier = SUNMatScaleAdd(c, A, B); Performs the operation $A = cA + B$ . The return value is an integer flag denoting success/failure of the operation.
SUNMatScaleAddI	ier = SUNMatScaleAddI(c, A); Performs the operation $A = cA + I$ . The return value is an integer flag denoting success/failure of the operation.
SUNMatMatvec	ier = SUNMatMatvec(A, x, y); Performs the matrix-vector product operation, $y = Ax$ . It should only be called with vectors x and y that are compatible with the matrix A – both in storage type and dimensions. The return value is an integer flag denoting success/failure of the operation.

We note that not all SUNMATRIX types are compatible with all NVECTOR types provided with SUNDIALS. This is primarily due to the need for compatibility within the SUNMatMatvec routine; however, compatibility between SUNMATRIX and NVECTOR implementations is more crucial when considering their interaction within SUNLINSOL objects, as will be described in more detail in Chapter 9. More specifically, in Table 8.3 we show the matrix interfaces available as SUNMATRIX modules, and the compatible vector implementations.

Table 8.3: SUNDIALS matrix interfaces and vector implementations that can be used for each.

## 8.1 The SUNMatrix\_Dense implementation

The dense implementation of the SUNMATRIX module provided with SUNDIALS, SUNMATRIX\_DENSE, defines the *content* field of SUNMatrix to be the following structure:

```
struct _SUNMatrixContent_Dense {
   sunindextype M;
   sunindextype N;
   realtype *data;
   sunindextype ldata;
   realtype **cols;
};
```

These entries of the *content* field contain the following information:

M - number of rows

N - number of columns

data - pointer to a contiguous block of realtype variables. The elements of the dense matrix are stored columnwise, i.e. the (i,j)-th element of a dense SUNMATRIX A (with  $0 \le i < M$  and  $0 \le j < N$ ) may be accessed via data[j\*M+i].

**ldata** - length of the data array  $(= M \cdot N)$ .

cols - array of pointers. cols[j] points to the first element of the j-th column of the matrix in the array data. The (i,j)-th element of a dense SUNMATRIX A (with  $0 \le i < M$  and  $0 \le j < N$ ) may be accessed via cols[j][i].

The header file to include when using this module is sunmatrix/sunmatrix\_dense.h. The SUNMATRIX\_DENSE module is accessible from all SUNDIALS solvers without linking to the libsundials\_sunmatrixdense module library.

The following macros are provided to access the content of a SUNMATRIX\_DENSE matrix. The prefix  $SM_{-}$  in the names denotes that these macros are for SUNMatrix implementations, and the suffix D denotes that these are specific to the dense version.

#### • SM\_CONTENT\_D

This macro gives access to the contents of the dense SUNMatrix.

The assignment  $A\_cont = SM\_CONTENT\_D(A)$  sets  $A\_cont$  to be a pointer to the dense SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_D(A) ( (SUNMatrixContent_Dense)(A->content) )
```

• SM\_ROWS\_D, SM\_COLUMNS\_D, and SM\_LDATA\_D

These macros give individual access to various lengths relevant to the content of a dense SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A\_rows = SM\_ROWS\_D(A) sets A\_rows to be the number of rows in the matrix A. Similarly, the assignment SM\_COLUMNS\_D(A) = A\_cols sets the number of columns in A to equal A\_cols.

Implementation:

#### • SM\_DATA\_D and SM\_COLS\_D

These macros give access to the data and cols pointers for the matrix entries.

The assignment A\_data = SM\_DATA\_D(A) sets A\_data to be a pointer to the first component of the data array for the dense SUNMatrix A. The assignment SM\_DATA\_D(A) = A\_data sets the data array of A to be A\_data by storing the pointer A\_data.

Similarly, the assignment  $A\_cols = SM\_COLS\_D(A)$  sets  $A\_cols$  to be a pointer to the array of column pointers for the dense SUNMatrix A. The assignment  $SM\_COLS\_D(A) = A\_cols$  sets the column pointer array of A to be  $A\_cols$  by storing the pointer  $A\_cols$ .

Implementation:

```
#define SM_DATA_D(A) ( SM_CONTENT_D(A)->data )
#define SM_COLS_D(A) ( SM_CONTENT_D(A)->cols )
```

#### SM\_COLUMN\_D and SM\_ELEMENT\_D

These macros give access to the individual columns and entries of the data array of a dense SUNMatrix.

The assignment col\_j = SM\_COLUMN\_D(A,j) sets col\_j to be a pointer to the first entry of the j-th column of the M  $\times$  N dense matrix A (with  $0 \le j < N$ ). The type of the expression SM\_COLUMN\_D(A,j) is realtype \*. The pointer returned by the call SM\_COLUMN\_D(A,j) can be treated as an array which is indexed from 0 to M - 1.

The assignments SM\_ELEMENT\_D(A,i,j) = a\_ij and a\_ij = SM\_ELEMENT\_D(A,i,j) reference the (i,j)-th element of the M × N dense matrix A (with  $0 \le i < M$  and  $0 \le j < N$ ).

Implementation:

```
#define SM_COLUMN_D(A,j) ( (SM_CONTENT_D(A)->cols)[j] )
#define SM_ELEMENT_D(A,i,j) ( (SM_CONTENT_D(A)->cols)[j][i] )
```

The SUNMATRIX\_DENSE module defines dense implementations of all matrix operations listed in Table 8.2. Their names are obtained from those in Table 8.2 by appending the suffix \_Dense (e.g. SUNMatCopy\_Dense). The module SUNMATRIX\_DENSE provides the following additional user-callable routines:

#### • SUNDenseMatrix

This constructor function creates and allocates memory for a dense SUNMatrix. Its arguments are the number of rows, M, and columns, N, for the dense matrix.

```
SUNMatrix SUNDenseMatrix(sunindextype M, sunindextype N);
```

#### • SUNDenseMatrix\_Print

This function prints the content of a dense SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

```
void SUNDenseMatrix_Print(SUNMatrix A, FILE* outfile);
```

#### • SUNDenseMatrix\_Rows

This function returns the number of rows in the dense SUNMatrix. sunindextype SUNDenseMatrix\_Rows(SUNMatrix A);

• SUNDenseMatrix\_Columns

This function returns the number of columns in the dense SUNMatrix. sunindextype SUNDenseMatrix\_Columns(SUNMatrix A);

• SUNDenseMatrix\_LData

This function returns the length of the data array for the dense SUNMatrix. sunindextype SUNDenseMatrix\_LData(SUNMatrix A);

• SUNDenseMatrix\_Data

This function returns a pointer to the data array for the dense SUNMatrix. realtype\* SUNDenseMatrix\_Data(SUNMatrix A);

• SUNDenseMatrix\_Cols

This function returns a pointer to the cols array for the dense SUNMatrix. realtype\*\* SUNDenseMatrix\_Cols(SUNMatrix A);

• SUNDenseMatrix\_Column

This function returns a pointer to the first entry of the jth column of the dense SUNMatrix. The resulting pointer should be indexed over the range 0 to M-1.

```
realtype* SUNDenseMatrix_Column(SUNMatrix A, sunindextype j);
```

#### Notes

- When looping over the components of a dense SUNMatrix A, the most efficient approaches are to:
  - First obtain the component array via A\_data = SM\_DATA\_D(A) or A\_data = SUNDenseMatrix\_Data(A) and then access A\_data[i] within the loop.
  - First obtain the array of column pointers via A\_cols = SM\_COLS\_D(A) or A\_cols = SUNDenseMatrix\_Cols(A), and then access A\_cols[j][i] within the loop.
  - Within a loop over the columns, access the column pointer via
     A\_colj = SUNDenseMatrix\_Column(A,j) and then to access the entries within that column using A\_colj[i] within the loop.

All three of these are more efficient than using SM\_ELEMENT\_D(A,i,j) within a double loop.

• Within the SUNMatMatvec\_Dense routine, internal consistency checks are performed to ensure that the matrix is called with consistent NVECTOR implementations. These are currently limited to: NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS. As additional compatible vector implementations are added to SUNDIALS, these will be included within this compatibility check.

For solvers that include a Fortran interface module, the SUNMATRIX\_DENSE module also includes the Fortran-callable function FSUNDenseMatInit(code, M, N, ier) to initialize this SUNMATRIX\_DENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); M and N are the corresponding dense matrix construction arguments (declared to match C type long int); and ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNDenseMassMatInit(M, N, ier) initializes this SUNMATRIX\_DENSE module for storing the mass matrix.

### 8.2 The SUNMatrix\_Band implementation

The banded implementation of the SUNMATRIX module provided with SUNDIALS, SUNMATRIX\_BAND, defines the *content* field of SUNMatrix to be the following structure:

```
struct _SUNMatrixContent_Band {
   sunindextype M;
   sunindextype N;
   sunindextype mu;
   sunindextype ml;
   sunindextype s_mu;
   sunindextype ldim;
   realtype *data;
   sunindextype ldata;
   realtype **cols;
};
```

A diagram of the underlying data representation in a banded matrix is shown in Figure 8.1. A more complete description of the parts of this *content* field is given below:

```
M - number of rows N \text{ - number of columns } (\mathtt{N} = \mathtt{M}) mu \text{ - upper half-bandwidth, } 0 \leq \mathtt{mu} < \mathtt{N} ml \text{ - lower half-bandwidth, } 0 \leq \mathtt{m1} < \mathtt{N}
```

s\_mu - storage upper bandwidth, mu ≤ s\_mu < N. The LU decomposition routines in the associated SUNLINSOL\_BAND and SUNLINSOL\_LAPACKBAND modules write the LU factors into the storage for A. The upper triangular factor U, however, may have an upper bandwidth as big as min(N-1,mu+ml) because of partial pivoting. The s\_mu field holds the upper half-bandwidth allocated for A.</p>

```
ldim - leading dimension (ldim \ge s_mu+ml+1)
```

data - pointer to a contiguous block of realtype variables. The elements of the banded matrix are stored columnwise (i.e. columns are stored one on top of the other in memory). Only elements within the specified half-bandwidths are stored. data is a pointer to ldata contiguous locations which hold the elements within the band of A.

```
ldata - length of the data array (= ldim \cdot N)
```

cols - array of pointers. cols[j] is a pointer to the uppermost element within the band in the j-th column. This pointer may be treated as an array indexed from  $s_mu-mu$  (to access the uppermost element within the band in the j-th column) to  $s_mu+ml$  (to access the lowest element within the band in the j-th column). Indices from 0 to  $s_mu-mu-1$  give access to extra storage elements required by the LU decomposition function. Finally,  $cols[j][i-j+s_mu]$  is the (i,j)-th element with  $j-mu \le i \le j+ml$ .

The header file to include when using this module is sunmatrix/sunmatrix\_band.h. The SUNMATRIX\_BAND module is accessible from all SUNDIALS solvers without linking to the libsundials\_sunmatrixband module library.

The following macros are provided to access the content of a SUNMATRIX\_BAND matrix. The prefix SM\_ in the names denotes that these macros are for *SUNMatrix* implementations, and the suffix \_B denotes that these are specific to the *banded* version.

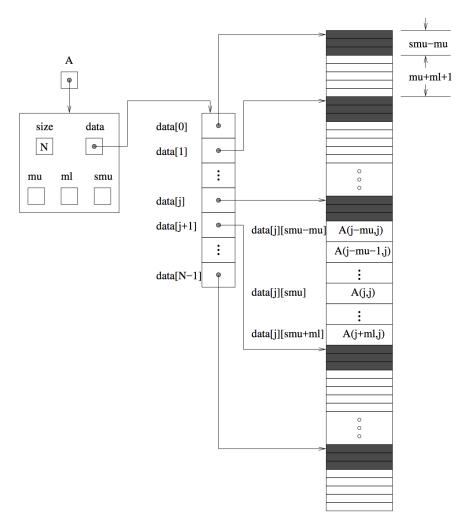

Figure 8.1: Diagram of the storage for the SUNMATRIX\_BAND module. Here A is an N  $\times$  N band matrix with upper and lower half-bandwidths mu and ml, respectively. The rows and columns of A are numbered from 0 to N - 1 and the (i,j)-th element of A is denoted A(i,j). The greyed out areas of the underlying component storage are used by the associated SUNLINSOL\_BAND linear solver.

#### • SM\_CONTENT\_B

This routine gives access to the contents of the banded SUNMatrix.

The assignment A\_cont = SM\_CONTENT\_B(A) sets A\_cont to be a pointer to the banded SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_B(A) ( (SUNMatrixContent_Band) (A->content) )
```

SM\_ROWS\_B, SM\_COLUMNS\_B, SM\_UBAND\_B, SM\_LBAND\_B, SM\_SUBAND\_B, SM\_LDIM\_B, and SM\_LDATA\_B
 These macros give individual access to various lengths relevant to the content of a banded SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A\_rows = SM\_ROWS\_B(A) sets A\_rows to be the number of rows in the matrix A. Similarly, the assignment SM\_COLUMNS\_B(A) = A\_cols sets the number of columns in A to equal A\_cols.

Implementation:

```
#define SM_ROWS_B(A) ( SM_CONTENT_B(A)->M )
#define SM_COLUMNS_B(A) ( SM_CONTENT_B(A)->N )
#define SM_UBAND_B(A) ( SM_CONTENT_B(A)->mu )
#define SM_LBAND_B(A) ( SM_CONTENT_B(A)->ml )
#define SM_SUBAND_B(A) ( SM_CONTENT_B(A)->s_mu )
#define SM_LDIM_B(A) ( SM_CONTENT_B(A)->ldim )
#define SM_LDATA_B(A) ( SM_CONTENT_B(A)->ldata )
```

#### • SM\_DATA\_B and SM\_COLS\_B

These macros give access to the data and cols pointers for the matrix entries.

The assignment A\_data = SM\_DATA\_B(A) sets A\_data to be a pointer to the first component of the data array for the banded SUNMatrix A. The assignment SM\_DATA\_B(A) = A\_data sets the data array of A to be A\_data by storing the pointer A\_data.

Similarly, the assignment A\_cols = SM\_COLS\_B(A) sets A\_cols to be a pointer to the array of column pointers for the banded SUNMatrix A. The assignment SM\_COLS\_B(A) = A\_cols sets the column pointer array of A to be A\_cols by storing the pointer A\_cols.

Implementation:

```
#define SM_DATA_B(A) ( SM_CONTENT_B(A)->data )
#define SM_COLS_B(A) ( SM_CONTENT_B(A)->cols )
```

• SM\_COLUMN\_B, SM\_COLUMN\_ELEMENT\_B, and SM\_ELEMENT\_B

These macros give access to the individual columns and entries of the data array of a banded SUNMatrix.

The assignments SM\_ELEMENT\_B(A,i,j) = a\_ij and a\_ij = SM\_ELEMENT\_B(A,i,j) reference the (i,j)-th element of the N × N band matrix A, where  $0 \le i, j \le N-1$ . The location (i,j) should further satisfy  $j-mu \le i \le j+ml$ .

The assignment  $col_j = SM\_COLUMN\_B(A,j)$  sets  $col_j$  to be a pointer to the diagonal element of the j-th column of the N × N band matrix A,  $0 \le j \le N-1$ . The type of the expression  $SM\_COLUMN\_B(A,j)$  is realtype \*. The pointer returned by the call  $SM\_COLUMN\_B(A,j)$  can be treated as an array which is indexed from -mu to ml.

The assignments SM\_COLUMN\_ELEMENT\_B(col\_j,i,j) = a\_ij and

a\_ij = SM\_COLUMN\_ELEMENT\_B(col\_j,i,j) reference the (i,j)-th entry of the band matrix A when used in conjunction with SM\_COLUMN\_B to reference the j-th column through col\_j. The index (i,j) should satisfy  $j-mu \le i \le j+ml$ .

Implementation:

The SUNMATRIX\_BAND module defines banded implementations of all matrix operations listed in Table 8.2. Their names are obtained from those in Table 8.2 by appending the suffix \_Band (e.g. SUNMatCopy\_Band). The module SUNMATRIX\_BAND provides the following additional user-callable routines:

#### • SUNBandMatrix

This constructor function creates and allocates memory for a banded SUNMatrix. Its arguments are the matrix size, N, the upper and lower half-bandwidths of the matrix, mu and ml, and the stored upper bandwidth, smu. When creating a band SUNMatrix, this value should be

- at least min(N-1,mu+ml) if the matrix will be used by the SUNLINSOL\_BAND module;
- exactly equal to mu+ml if the matrix will be used by the SUNLINSOL\_LAPACKBAND module;
- at least mu if used in some other manner.

```
SUNMatrix SUNBandMatrix(sunindextype N, sunindextype mu, sunindextype ml, sunindextype smu);
```

#### • SUNBandMatrix\_Print

This function prints the content of a banded SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

```
void SUNBandMatrix_Print(SUNMatrix A, FILE* outfile);
```

#### • SUNBandMatrix\_Rows

This function returns the number of rows in the banded SUNMatrix. sunindextype SUNBandMatrix\_Rows(SUNMatrix A);

#### • SUNBandMatrix\_Columns

This function returns the number of columns in the banded SUNMatrix. sunindextype SUNBandMatrix\_Columns(SUNMatrix A);

#### • SUNBandMatrix\_LowerBandwidth

This function returns the lower half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix\_LowerBandwidth(SUNMatrix A);

#### • SUNBandMatrix\_UpperBandwidth

This function returns the upper half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix\_UpperBandwidth(SUNMatrix A);

#### • SUNBandMatrix\_StoredUpperBandwidth

This function returns the stored upper half-bandwidth of the banded SUNMatrix. sunindextype SUNBandMatrix\_StoredUpperBandwidth(SUNMatrix A);

• SUNBandMatrix\_LDim

This function returns the length of the leading dimension of the banded SUNMatrix.sunindextype SUNBandMatrix\_LDim(SUNMatrix A);

• SUNBandMatrix\_Data

This function returns a pointer to the data array for the banded SUNMatrix.realtype\* SUNBandMatrix\_Data(SUNMatrix A);

• SUNBandMatrix\_Cols

This function returns a pointer to the cols array for the banded  ${\tt SUNMatrix}$ .

```
realtype** SUNBandMatrix_Cols(SUNMatrix A);
```

• SUNBandMatrix\_Column

This function returns a pointer to the diagonal entry of the j-th column of the banded SUNMatrix. The resulting pointer should be indexed over the range —mu to ml.

```
realtype* SUNBandMatrix_Column(SUNMatrix A, sunindextype j);
```

#### Notes

- When looping over the components of a banded SUNMatrix A, the most efficient approaches are to:
  - First obtain the component array via A\_data = SM\_DATA\_B(A) or A\_data = SUNBandMatrix\_Data(A) and then access A\_data[i] within the loop.
  - First obtain the array of column pointers via A\_cols = SM\_COLS\_B(A) or A\_cols = SUNBandMatrix\_Cols(A), and then access A\_cols[j][i] within the loop.
  - Within a loop over the columns, access the column pointer via
     A\_colj = SUNBandMatrix\_Column(A,j) and then to access the entries within that column using SM\_COLUMN\_ELEMENT\_B(A\_colj,i,j).

All three of these are more efficient than using SM\_ELEMENT\_B(A,i,j) within a double loop.

• Within the SUNMatMatvec\_Band routine, internal consistency checks are performed to ensure that the matrix is called with consistent NVECTOR implementations. These are currently limited to: NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS. As additional compatible vector implementations are added to SUNDIALS, these will be included within this compatibility check.

For solvers that include a Fortran interface module, the SUNMATRIX\_BAND module also includes the Fortran-callable function FSUNBandMatInit(code, N, mu, ml, smu, ier) to initialize this SUNMATRIX\_BAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); N, mu, ml and smu are the corresponding band matrix construction arguments (declared to match C type long int); and ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNBandMassMatInit(N, mu, ml, smu, ier) initializes this SUNMATRIX\_BAND module for storing the mass matrix.

# 8.3 The SUNMatrix\_Sparse implementation

The sparse implementation of the Sunmatrix module provided with Sundials, Sunmatrix\_sparse, is designed to work with either *compressed-sparse-column* (CSC) or *compressed-sparse-row* (CSR) sparse matrix formats. To this end, it defines the *content* field of Sunmatrix to be the following structure:

```
struct _SUNMatrixContent_Sparse {
  sunindextype M;
  sunindextype N;
  sunindextype NNZ;
  sunindextype NP;
  realtype *data;
  int sparsetype;
  sunindextype *indexvals;
  sunindextype *indexptrs;
  /* CSC indices */
  sunindextype **rowvals;
  sunindextype **colptrs;
  /* CSR indices */
  sunindextype **colvals;
  sunindextype **rowptrs;
};
```

A diagram of the underlying data representation for a CSC matrix is shown in Figure 8.2 (the CSR format is similar). A more complete description of the parts of this *content* field is given below:

M - number of rows

 ${f N}$  - number of columns

NNZ - maximum number of nonzero entries in the matrix (allocated length of data and indexvals arrays)

NP - number of index pointers (e.g. number of column pointers for CSC matrix). For CSC matrices NP = N, and for CSR matrices NP = M. This value is set automatically based the input for sparsetype.

data - pointer to a contiguous block of realtype variables (of length NNZ), containing the values of the nonzero entries in the matrix

sparsetype - type of the sparse matrix (CSC\_MAT or CSR\_MAT)

indexvals - pointer to a contiguous block of int variables (of length NNZ), containing the row indices
 (if CSC) or column indices (if CSR) of each nonzero matrix entry held in data

indexptrs - pointer to a contiguous block of int variables (of length NP+1). For CSC matrices each entry provides the index of the first column entry into the data and indexvals arrays, e.g. if indexptr[3]=7, then the first nonzero entry in the fourth column of the matrix is located in data[7], and is located in row indexvals[7] of the matrix. The last entry contains the total number of nonzero values in the matrix and hence points one past the end of the active data in the data and indexvals arrays. For CSR matrices, each entry provides the index of the first row entry into the data and indexvals arrays.

The following pointers are added to the SlsMat type for user convenience, to provide a more intuitive interface to the CSC and CSR sparse matrix data structures. They are set automatically when creating a sparse SUNMATRIX, based on the sparse matrix storage type.

rowvals - pointer to indexvals when sparsetype is CSC\_MAT, otherwise set to NULL.

colptrs - pointer to indexptrs when sparsetype is CSC\_MAT, otherwise set to NULL.

colvals - pointer to indexvals when sparsetype is CSR\_MAT, otherwise set to NULL.

rowptrs - pointer to indexptrs when sparsetype is CSR\_MAT, otherwise set to NULL.

For example, the  $5 \times 4$  CSC matrix

$$\left[\begin{array}{cccc} 0 & 3 & 1 & 0 \\ 3 & 0 & 0 & 2 \\ 0 & 7 & 0 & 0 \\ 1 & 0 & 0 & 9 \\ 0 & 0 & 0 & 5 \end{array}\right]$$

could be stored in this structure as either

```
M = 5;
 N = 4;
  NNZ = 8;
  NP = N;
  data = \{3.0, 1.0, 3.0, 7.0, 1.0, 2.0, 9.0, 5.0\};
  sparsetype = CSC_MAT;
  indexvals = \{1, 3, 0, 2, 0, 1, 3, 4\};
  indexptrs = \{0, 2, 4, 5, 8\};
or
 M = 5;
  N = 4;
  NNZ = 10;
  NP = N;
  data = \{3.0, 1.0, 3.0, 7.0, 1.0, 2.0, 9.0, 5.0, *, *\};
  sparsetype = CSC_MAT;
  indexvals = \{1, 3, 0, 2, 0, 1, 3, 4, *, *\};
  indexptrs = \{0, 2, 4, 5, 8\};
```

where the first has no unused space, and the second has additional storage (the entries marked with \* may contain any values). Note in both cases that the final value in indexptrs is 8, indicating the total number of nonzero entries in the matrix.

Similarly, in CSR format, the same matrix could be stored as

```
M = 5;
N = 4;
NNZ = 8;
NP = N;
data = {3.0, 1.0, 3.0, 2.0, 7.0, 1.0, 9.0, 5.0};
sparsetype = CSR_MAT;
indexvals = {1, 2, 0, 3, 1, 0, 3, 3};
indexptrs = {0, 2, 4, 5, 7, 8};
```

The header file to include when using this module is sunmatrix/sunmatrix\_sparse.h. The SUNMATRIX\_SPARSE module is accessible from all SUNDIALS solvers without linking to the libsundials\_sunmatrixsparse module library.

The following macros are provided to access the content of a SUNMATRIX\_SPARSE matrix. The prefix SM\_ in the names denotes that these macros are for *SUNMatrix* implementations, and the suffix \_S denotes that these are specific to the *sparse* version.

#### • SM\_CONTENT\_S

This routine gives access to the contents of the sparse SUNMatrix.

The assignment  $A_{cont} = SM_{cont} = SM_{cont} = SM_{cont}$  sets  $A_{cont}$  to be a pointer to the sparse SUNMatrix content structure.

Implementation:

```
#define SM_CONTENT_S(A) ( (SUNMatrixContent_Sparse) (A->content) )
```

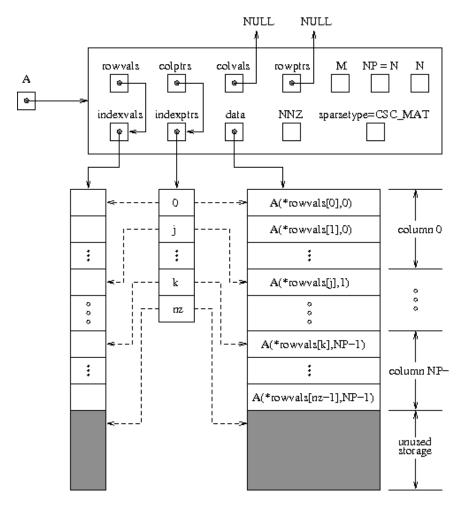

Figure 8.2: Diagram of the storage for a compressed-sparse-column matrix. Here A is an  $M \times N$  sparse matrix with storage for up to NNZ nonzero entries (the allocated length of both data and indexvals). The entries in indexvals may assume values from 0 to M-1, corresponding to the row index (zero-based) of each nonzero value. The entries in data contain the values of the nonzero entries, with the row i, column j entry of A (again, zero-based) denoted as A(i,j). The indexptrs array contains N+1 entries; the first N denote the starting index of each column within the indexvals and data arrays, while the final entry points one past the final nonzero entry. Here, although NNZ values are allocated, only nz are actually filled in; the greyed-out portions of data and indexvals indicate extra allocated space.

#### • SM\_ROWS\_S, SM\_COLUMNS\_S, SM\_NNZ\_S, SM\_NP\_S, and SM\_SPARSETYPE\_S

These macros give individual access to various lengths relevant to the content of a sparse SUNMatrix.

These may be used either to retrieve or to set these values. For example, the assignment A\_rows = SM\_ROWS\_S(A) sets A\_rows to be the number of rows in the matrix A. Similarly, the assignment SM\_COLUMNS\_S(A) = A\_cols sets the number of columns in A to equal A\_cols.

Implementation:

```
#define SM_ROWS_S(A) ( SM_CONTENT_S(A)->M )
#define SM_COLUMNS_S(A) ( SM_CONTENT_S(A)->N )
#define SM_NNZ_S(A) ( SM_CONTENT_S(A)->NNZ )
#define SM_NP_S(A) ( SM_CONTENT_S(A)->NP )
#define SM_SPARSETYPE_S(A) ( SM_CONTENT_S(A)->sparsetype )
```

#### • SM\_DATA\_S, SM\_INDEXVALS\_S, and SM\_INDEXPTRS\_S

These macros give access to the data and index arrays for the matrix entries.

The assignment A\_data = SM\_DATA\_S(A) sets A\_data to be a pointer to the first component of the data array for the sparse SUNMatrix A. The assignment SM\_DATA\_S(A) = A\_data sets the data array of A to be A\_data by storing the pointer A\_data.

Similarly, the assignment A\_indexvals = SM\_INDEXVALS\_S(A) sets A\_indexvals to be a pointer to the array of index values (i.e. row indices for a CSC matrix, or column indices for a CSR matrix) for the sparse SUNMatrix A. The assignment A\_indexptrs = SM\_INDEXPTRS\_S(A) sets A\_indexptrs to be a pointer to the array of index pointers (i.e. the starting indices in the data/indexvals arrays for each row or column in CSR or CSC formats, respectively).

Implementation:

```
#define SM_DATA_S(A) ( SM_CONTENT_S(A)->data )
#define SM_INDEXVALS_S(A) ( SM_CONTENT_S(A)->indexvals )
#define SM_INDEXPTRS_S(A) ( SM_CONTENT_S(A)->indexptrs )
```

The SUNMATRIX\_SPARSE module defines sparse implementations of all matrix operations listed in Table 8.2. Their names are obtained from those in Table 8.2 by appending the suffix \_Sparse (e.g. SUNMatCopy\_Sparse). The module SUNMATRIX\_SPARSE provides the following additional user-callable routines:

#### • SUNSparseMatrix

This function creates and allocates memory for a sparse SUNMatrix. Its arguments are the number of rows and columns of the matrix, M and N, the maximum number of nonzeros to be stored in the matrix, NNZ, and a flag sparsetype indicating whether to use CSR or CSC format (valid arguments are CSR\_MAT or CSC\_MAT).

```
SUNMatrix SUNSparseMatrix(sunindextype M, sunindextype N, sunindextype NNZ, int sparsetype);
```

#### • SUNSparseFromDenseMatrix

This function creates a new sparse matrix from an existing dense matrix by copying all values with magnitude larger than droptol into the sparse matrix structure.

Requirements:

- A must have type SUNMATRIX\_DENSE;

- droptol must be non-negative;
- sparsetype must be either CSC\_MAT or CSR\_MAT.

The function returns NULL if any requirements are violated, or if the matrix storage request cannot be satisfied.

SUNMatrix SUNSparseFromDenseMatrix(SUNMatrix A, realtype droptol, int sparsetype);

#### • SUNSparseFromBandMatrix

This function creates a new sparse matrix from an existing band matrix by copying all values with magnitude larger than droptol into the sparse matrix structure.

Requirements:

- A must have type SUNMATRIX\_BAND;
- droptol must be non-negative;
- sparsetype must be either CSC\_MAT or CSR\_MAT.

The function returns NULL if any requirements are violated, or if the matrix storage request cannot be satisfied.

#### • SUNSparseMatrix\_Realloc

This function reallocates internal storage arrays in a sparse matrix so that the resulting sparse matrix has no wasted space (i.e. the space allocated for nonzero entries equals the actual number of nonzeros, indexptrs[NP]). Returns 0 on success and 1 on failure (e.g. if the input matrix is not sparse).

int SUNSparseMatrix\_Realloc(SUNMatrix A);

#### • SUNSparseMatrix\_Reallocate

This function reallocates internal storage arrays in a sparse matrix so that the resulting sparse matrix has storage for a specified number of nonzeros. Returns 0 on success and 1 on failure (e.g. if the input matrix is not sparse or if NNZ is negative).

int SUNSparseMatrix\_Reallocate(SUNMatrix A, sunindextype NNZ);

#### • SUNSparseMatrix\_Print

This function prints the content of a sparse SUNMatrix to the output stream specified by outfile. Note: stdout or stderr may be used as arguments for outfile to print directly to standard output or standard error, respectively.

void SUNSparseMatrix\_Print(SUNMatrix A, FILE\* outfile);

#### • SUNSparseMatrix\_Rows

This function returns the number of rows in the sparse SUNMatrix.

sunindextype SUNSparseMatrix\_Rows(SUNMatrix A);

#### • SUNSparseMatrix\_Columns

This function returns the number of columns in the sparse SUNMatrix.

sunindextype SUNSparseMatrix\_Columns(SUNMatrix A);

#### • SUNSparseMatrix\_NNZ

This function returns the number of entries allocated for nonzero storage for the sparse matrix SUNMatrix.

sunindextype SUNSparseMatrix\_NNZ(SUNMatrix A);

#### • SUNSparseMatrix\_NP

This function returns the number of columns/rows for the sparse SUNMatrix, depending on whether the matrix uses CSC/CSR format, respectively. The indexptrs array has NP+1 entries. sunindextype SUNSparseMatrix\_NP(SUNMatrix A);

#### • SUNSparseMatrix\_SparseType

This function returns the storage type (CSR\_MAT or CSC\_MAT) for the sparse SUNMatrix. int SUNSparseMatrix\_SparseType(SUNMatrix A);

#### • SUNSparseMatrix\_Data

This function returns a pointer to the data array for the sparse SUNMatrix. realtype\* SUNSparseMatrix\_Data(SUNMatrix A);

#### • SUNSparseMatrix\_IndexValues

This function returns a pointer to index value array for the sparse SUNMatrix: for CSR format this is the column index for each nonzero entry, for CSC format this is the row index for each nonzero entry.

sunindextype\* SUNSparseMatrix\_IndexValues(SUNMatrix A);

#### • SUNSparseMatrix\_IndexPointers

This function returns a pointer to the index pointer array for the sparse SUNMatrix: for CSR format this is the location of the first entry of each row in the data and indexvalues arrays, for CSC format this is the location of the first entry of each column.

```
sunindextype* SUNSparseMatrix_IndexPointers(SUNMatrix A);
```

Within the SUNMatMatvec\_Sparse routine, internal consistency checks are performed to ensure that the matrix is called with consistent NVECTOR implementations. These are currently limited to: NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS. As additional compatible vector implementations are added to SUNDIALS, these will be included within this compatibility check.

For solvers that include a Fortran interface module, the SUNMATRIX\_SPARSE module also includes the Fortran-callable function FSUNSparseMatInit(code, M, N, NNZ, sparsetype, ier) to initialize this SUNMATRIX\_SPARSE module for a given SUNDIALS solver. Here code is an integer input for the solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); M, N and NNZ are the corresponding sparse matrix construction arguments (declared to match C type long int); sparsetype is an integer flag indicating the sparse storage type (0 for CSC, 1 for CSR); and ier is an error return flag equal to 0 for success and -1 for failure. Each of code, sparsetype and ier are declared so as to match C type int. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNSparseMassMatInit(M, N, NNZ, sparsetype, ier) initializes this SUNMATRIX\_SPARSE module for storing the mass matrix.

# 8.4 SUNMatrix Examples

There are SUNMatrix examples that may be installed for each implementation: dense, banded, and sparse. Each implementation makes use of the functions in test\_sunmatrix.c. These example functions show simple usage of the SUNMatrix family of functions. The inputs to the examples depend on the matrix type, and are output to stdout if the example is run without the appropriate number of command-line arguments.

The following is a list of the example functions in test\_sunmatrix.c:

- Test\_SUNMatGetID: Verifies the returned matrix ID against the value that should be returned.
- Test\_SUNMatClone: Creates clone of an existing matrix, copies the data, and checks that their values match.
- Test\_SUNMatZero: Zeros out an existing matrix and checks that each entry equals 0.0.
- Test\_SUNMatCopy: Clones an input matrix, copies its data to a clone, and verifies that all values match.
- Test\_SUNMatScaleAdd: Given an input matrix A and an input identity matrix I, this test clones and copies A to a new matrix B, computes B = -B + B, and verifies that the resulting matrix entries equal 0.0. Additionally, if the matrix is square, this test clones and copies A to a new matrix D, clones and copies I to a new matrix C, computes D = D + I and C = C + A using SUNMatScaleAdd, and then verifies that C == D.
- Test\_SUNMatScaleAddI: Given an input matrix A and an input identity matrix I, this clones and copies I to a new matrix B, computes B = -B + I using SUNMatScaleAddI, and verifies that the resulting matrix entries equal 0.0.
- Test\_SUNMatMatvec Given an input matrix A and input vectors x and y such that y = Ax, this test has different behavior depending on whether A is square. If it is square, it clones and copies A to a new matrix B, computes B = 3B + I using SUNMatScaleAddI, clones y to new vectors w and z, computes z = Bx using SUNMatMatvec, computes w = 3y + x using N\_VLinearSum, and verifies that w == z. If A is not square, it just clones y to a new vector z, computes z = Ax using SUNMatMatvec, and verifies that y == z.
- Test\_SUNMatSpace verifies that SUNMatSpace can be called, and outputs the results to stdout.

# 8.5 SUNMatrix functions used by CVODES

In Table 8.4 below, we list the matrix functions in the SUNMATRIX module used within the CVODES package. The table also shows, for each function, which of the code modules uses the function. Neither the main CVODES integrator or the CVSPILS interface call SUNMATRIX functions directly, so the table columns are specific to the CVDLS direct solver interface and the CVBANDPRE and CVBBDPRE preconditioner modules.

At this point, we should emphasize that the CVODES user does not need to know anything about the usage of matrix functions by the CVODES code modules in order to use CVODES. The information is presented as an implementation detail for the interested reader.

	CVDLS	CVBANDPRE	CVBBDPRE
SUNMatGetID	<b>√</b>		
SUNMatClone	<b>√</b>		
SUNMatDestroy	<b>√</b>	✓	<b>√</b>
SUNMatZero	<b>√</b>	<b>√</b>	<b>√</b>
SUNMatCopy	<b>√</b>	<b>√</b>	<b>√</b>
SUNMatScaleAddI	<b>√</b>	<b>√</b>	<b>√</b>
SUNMatSpace	†	†	†

Table 8.4: List of matrix functions usage by CVODES code modules

The matrix functions listed in Table 8.2 with a † symbol are optionally used, in that these are only called if they are implemented in the SUNMATRIX module that is being used (i.e. their function pointers are non-NULL). The matrix functions listed in Table 8.2 that are *not* used by CVODES are: SUNMatScaleAdd and SUNMatMatvec. Therefore a user-supplied SUNMATRIX module for CVODES could omit these functions.

# Chapter 9

# Description of the SUNLinearSolver module

For problems that involve the solution of linear systems of equations, the SUNDIALS solvers operate using generic linear solver modules (of type SUNLinearSolver), through a set of operations defined by the particular SUNLINSOL implementation. These work in coordination with the SUNDIALS generic NVECTOR and SUNMATRIX modules to provide a set of compatible data structures and solvers for the solution of linear systems using direct or iterative methods. Moreover, users can provide their own specific SUNLINSOL implementation to each SUNDIALS solver, particularly in cases where they provide their own NVECTOR and/or SUNMATRIX modules, and the customized linear solver leverages these additional data structures to create highly efficient and/or scalable solvers for their particular problem. Additionally, SUNDIALS provides native implementations SUNLINSOL modules, as well as SUNLINSOL modules that interface between SUNDIALS and external linear solver libraries.

The various SUNDIALS solvers have been designed to specifically leverage the use of either direct linear solvers or scaled, preconditioned, iterative linear solvers, through their "Dls" and "Spils" interfaces, respectively. Additionally, SUNDIALS solvers can make use of user-supplied custom linear solvers, whether these are problem-specific or come from external solver libraries.

For iterative (and possibly custom) linear solvers, the SUNDIALS solvers leverage scaling and preconditioning, as applicable, to balance error between solution components and to accelerate convergence of the linear solver. To this end, instead of solving the linear system Ax = b directly, we apply the underlying iterative algorithm to the transformed system

$$\tilde{A}\tilde{x} = \tilde{b} \tag{9.1}$$

where

$$\tilde{A} = S_1 P_1^{-1} A P_2^{-1} S_2^{-1},$$

$$\tilde{b} = S_1 P_1^{-1} b,$$

$$\tilde{x} = S_2 P_2 x,$$
(9.2)

and where

- $P_1$  is the left preconditioner,
- $P_2$  is the right preconditioner,
- $S_1$  is a diagonal matrix of scale factors for  $P_1^{-1}b$ ,
- $S_2$  is a diagonal matrix of scale factors for  $P_2x$ .

The SUNDIALS solvers request that iterative linear solvers stop based on the 2-norm of the scaled preconditioned residual meeting a prescribed tolerance

$$\left\| \tilde{b} - \tilde{A}\tilde{x} \right\|_{2} < \text{tol.}$$

We note that not all of the iterative linear solvers implemented in SUNDIALS support the full range of the above options. Similarly, some of the SUNDIALS integrators only utilize a subset of these options. Exceptions to the operators shown above are described in the documentation for each SUNLINSOL implementation, or for each SUNDIALS solver "Spils" interface.

The generic SUNLinearSolver type has been modeled after the object-oriented style of the generic N\_Vector type. Specifically, a generic SUNLinearSolver is a pointer to a structure that has an implementation-dependent *content* field containing the description and actual data of the linear solver, and an *ops* field pointing to a structure with generic linear solver operations. The type SUNLinearSolver is defined as

```
typedef struct _generic_SUNLinearSolver *SUNLinearSolver;
struct _generic_SUNLinearSolver {
  void *content;
  struct _generic_SUNLinearSolver_Ops *ops;
};
```

The \_generic\_SUNLinearSolver\_Ops structure is essentially a list of pointers to the various actual linear solver operations, and is defined as

```
struct _generic_SUNLinearSolver_Ops {
  SUNLinearSolver_Type (*gettype)(SUNLinearSolver);
                        (*setatimes)(SUNLinearSolver, void*, ATimesFn);
  int
  int
                        (*setpreconditioner)(SUNLinearSolver, void*,
                                             PSetupFn, PSolveFn);
                        (*setscalingvectors)(SUNLinearSolver,
  int
                                             N_Vector, N_Vector);
                        (*initialize)(SUNLinearSolver);
  int
                        (*setup)(SUNLinearSolver, SUNMatrix);
  int
  int
                        (*solve)(SUNLinearSolver, SUNMatrix, N_Vector,
                                 N_Vector, realtype);
  int
                        (*numiters)(SUNLinearSolver);
                        (*resnorm)(SUNLinearSolver);
  realtype
  long int
                        (*lastflag)(SUNLinearSolver);
  int
                        (*space)(SUNLinearSolver, long int*, long int*);
 N_Vector
                        (*resid)(SUNLinearSolver);
  int
                        (*free)(SUNLinearSolver);
};
```

The generic SUNLINSOL module defines and implements the linear solver operations acting on SUNLinearSolver objects. These routines are in fact only wrappers for the linear solver operations defined by a particular SUNLINSOL implementation, which are accessed through the *ops* field of the SUNLinearSolver structure. To illustrate this point we show below the implementation of a typical linear solver operation from the generic SUNLINSOL module, namely SUNLinSolInitialize, which initializes a SUNLINSOL object for use after it has been created and configured, and returns a flag denoting a successful/failed operation:

```
int SUNLinSolInitialize(SUNLinearSolver S)
{
  return ((int) S->ops->initialize(S));
}
```

Table 9.2 contains a complete list of all linear solver operations defined by the generic SUNLINSOL module. In order to support both direct and iterative linear solver types, the generic SUNLINSOL module defines linear solver routines (or arguments) that may be specific to individual use cases. As such, for each routine we specify its intended use. If a custom SUNLINSOL module is provided, the function pointers for non-required routines may be set to NULL to indicate that they are not provided.

A particular implementation of the Sunlinsol module must:

Table 9.1: Identifiers associated with linear solver kernels supplied with SUNDIALS.

Linear Solver ID	Solver type	ID Value
SUNLINEARSOLVER_DIRECT	Direct solvers	0
SUNLINEARSOLVER_ITERATIVE	Iterative solvers	1
SUNLINEARSOLVER_CUSTOM	Custom solvers	2

- Specify the *content* field of the SUNLinearSolver object.
- Define and implement a minimal subset of the linear solver operations. See the documentation for each SUNDIALS linear solver interface to determine which SUNLINSOL operations they require. Note that the names of these routines should be unique to that implementation in order to permit using more than one SUNLINSOL module (each with different SUNLinearSolver internal data representations) in the same code.
- Define and implement user-callable constructor and destructor routines to create and free a SUNLinearSolver with the new *content* field and with *ops* pointing to the new linear solver operations.
- Optionally, define and implement additional user-callable routines acting on the newly defined SUNLinearSolver (e.g., routines to set various configuration options for tuning the linear solver to a particular problem).
- Optionally, provide functions as needed for that particular implementation to access different parts in the *content* field of the newly defined SUNLinearSolver object (e.g., routines to return various statistics from the solver).

Each SUNLINSOL implementation included in SUNDIALS has a "type" identifier specified in enumeration and shown in Table 9.1. It is recommended that a user-supplied SUNLINSOL implementation set this identifier based on the SUNDIALS solver interface they intend to use: "Dls" interfaces require the SUNLINEARSOLVER\_DIRECT SUNLINSOL objects and "Spils" interfaces require the SUNLINEARSOLVER\_ITERATIVE objects.

Table 9.2: Description of the SUNLinearSolver operations

Name	Usage and Description
SUNLinSolGetType	type = SUNLinSolGetType(LS); Returns the type identifier for the linear solver LS. It is used to determine the solver type (direct, iterative, or custom) from the abstract SUNLinearSolver interface. This is used to assess compatibility with SUNDIALS-provided linear solver interfaces. Returned values are given in the Table 9.1.
	continued on next page

Name	Usage and Description
SUNLinSolInitialize	ier = SUNLinSolInitialize(LS); Performs linear solver initialization (assumes that all solver-specific options have been set). This should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 9.4.
SUNLinSolSetup	ier = SUNLinSolSetup(LS, A); Performs any linear solver setup needed, based on an updated system SUNMATRIX A. This may be called frequently (e.g. with a full Newton method) or infrequently (for a modified Newton method), based on the type of integrator and/or nonlinear solver requesting the solves. This should return zero for a successful call, a positive value for a recoverable failure and a negative value for an unrecoverable failure, ideally returning one of the generic error codes listed in Table 9.4.
SUNLinSolSolve	ier = SUNLinSolSolve(LS, A, x, b, tol); Solves a linear system $Ax = b$ . This should return zero for a successful call, a positive value for a recoverable failure and a negative value for an unrecoverable failure, ideally returning one of the generic error codes listed in Table 9.4.  Direct solvers: can ignore the realtype argument tol.  Iterative solvers: can ignore the SUNMATRIX input A since a NULL argument will be passed (these should instead rely on the matrix-vector product function supplied through the routine SUNLinSolSetATimes). These should attempt to solve to the specified realtype tolerance tol in a weighted 2-norm. If the solver does not support scaling then it should just use a 2-norm.  Custom solvers: all arguments will be supplied, and if the solver is approximate then it should attempt to solve to the specified realtype tolerance tol in a weighted 2-norm. If the solver does not support scaling then it should just use a 2-norm.
SUNLinSolFree	ier = SUNLinSolFree(LS); Frees memory allocated by the linear solver. This should return zero for a successful call, and a negative value for a failure.
SUNLinSolSetATimes	ier = SUNLinSolSetATimes(LS, A_data, ATimes); (Iterative/Custom linear solvers only) Provides ATimesFn function pointer, as well as a void * pointer to a data structure used by this routine, to a linear solver object. SUNDIALS solvers will call this function to set the matrix-vector product function to either a solver-provided difference-quotient via vector operations or a user-supplied solver-specific routine. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 9.4.
	continued on next page

Name	Usage and Description
SUNLinSolSetPreconditioner	ier = SUNLinSolSetPreconditioner(LS, Pdata, Pset, Psol); (Optional; Iterative/Custom linear solvers only) Provides PSetupFn and PSolveFn function pointers that implement the preconditioner solves $P_1^{-1}$ and $P_2^{-1}$ from equations (9.1)-(9.2). This routine will be called by a SUNDIALS solver, which will provide translation between the generic Pset and Psol calls and the integrator-specific and integrator- or user-supplied routines. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table 9.4.
SUNLinSolSetScalingVectors	ier = SUNLinSolSetScalingVectors (LS, $s1$ , $s2$ ); (Optional; Iterative/Custom linear solvers only) Sets pointers to left/right scaling vectors for the linear system solve. Here, $s1$ is an NVECTOR of positive scale factors containing the diagonal of the matrix $S_1$ from equations $(9.1)$ - $(9.2)$ . Similarly, $s2$ is an NVECTOR containing the diagonal of $S_2$ from equations $(9.1)$ - $(9.2)$ . Neither of these vectors are tested for positivity, and a NULL argument for either indicates that the corresponding scaling matrix is the identity. This routine should return zero for a successful call, and a negative value for a failure, ideally returning one of the generic error codes listed in Table $9.4$ .
SUNLinSolNumIters	its = SUNLinSolNumIters(LS); (Optional; Iterative/Custom linear solvers only) Should return the int number of linear iterations performed in the last 'solve' call.
SUNLinSolResNorm	<pre>rnorm = SUNLinSolResNorm(LS); (Optional; Iterative/Custom linear solvers only) Should return the realtype final residual norm from the last 'solve' call.</pre>
SUNLinSolResid	rvec = SUNLinSolResid(LS); (Optional; Iterative/Custom linear solvers only) If an iterative method computes the preconditioned initial residual and returns with a successful solve without performing any iterations (i.e. either the initial guess or the preconditioner is sufficiently accurate), then this function may be called by the SUNDIALS solver. This routine should return the NVECTOR containing the preconditioned initial residual vector.
	continued on next page

Name	Usage and Description
SUNLinLastFlag	lflag = SUNLinLastFlag(LS); (Optional) Should return the last error flag encountered within the linear solver. This is not called by the SUNDIALS solvers directly; it allows the user to investigate linear solver issues after a failed solve.
SUNLinSolSpace	ier = SUNLinSolSpace(LS, &lrw, &liw); (Optional) Returns the storage requirements for the linear solver LS. lrw is a long int containing the number of realtype words and liw is a long int containing the number of integer words. The return value is an integer flag denoting success/failure of the operation.  This function is advisory only, for use in determining a user's total space requirements.

# 9.1 Description of the client-supplied SUNLinearSolver routines

The SUNDIALS packages provide the ATimes, Pset and Psol routines utilized by the SUNLINSOL modules. These function types are defined in the header file sundials/sundials\_iterative.h, and are described here in case a user wishes to interact directly with an iterative SUNLINSOL object.

Definition typedef int (\*ATimesFn)(void \*A\_data, N\_Vector v, N\_Vector z);

Purpose These functions compute the action of a matrix on a vector, performing the operation

z=Av. Memory for  ${f z}$  should already be allocted prior to calling this function. The

vector v should be left unchanged.

Arguments A\_data is a pointer to client data, the same as that supplied to SUNLinSolSetATimes.

v is the input vector to multiply.

z is the output vector computed.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful.

Notes

PSetupFn

Definition typedef int (\*PSetupFn)(void \*P\_data)

Purpose These functions set up any requisite problem data in preparation for calls to the corre-

sponding PSolveFn.

Arguments P\_data is a pointer to client data, the same pointer as that supplied to the routine SUNLinSolSetPreconditioner.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful.

Notes

PSolveFn

Definition typedef int (\*PSolveFn)(void \*P\_data, N\_Vector r, N\_Vector z, realtype tol, int lr)

Purpose

These functions solve the preconditioner equation Pz = r for the vector z. Memory for z should already be allocted prior to calling this function. The parameter P\_data is a pointer to any information about P which the function needs in order to do its job (set up by the corresponding PSetupFn. The parameter 1r is input, and indicates whether P is to be taken as the left preconditioner or the right preconditioner: lr = 1 for left and 1r = 2 for right. If preconditioning is on one side only, 1r can be ignored. If the preconditioner is iterative, then it should strive to solve the preconditioner equation so that

$$||Pz - r||_{\text{wrms}} < tol$$

where the weight vector for the WRMS norm may be accessed from the main package memory structure. The vector r should not be modified by the PSolveFn.

Arguments

P\_data is a pointer to client data, the same pointer as that supplied to the routine SUNLinSolSetPreconditioner.

- is the right-hand side vector for the preconditioner system
- z is the solution vector for the preconditioner system

tol is the desired tolerance for an iterative preconditioner

1r is flag indicating whether the routine should perform left (1) or right (2) preconditioning.

Return value This routine should return 0 if successful and a non-zero value if unsuccessful. On a failure, a negative return value indicates an unrecoverable condition, while a positive value indicates a recoverable one, in which the calling routine may reattempt the solution after updating preconditioner data.

Notes

#### 9.2Compatibility of SUNLinear Solver modules

We note that not all SUNLINSOL types are compatible with all SUNMATRIX and NVECTOR types provided with SUNDIALS. In Table 9.3 we show the direct linear solvers available as SUNLINSOL modules, and the compatible matrix implementations. Recall that Table 4.1 shows the compatibility between all SUNLINSOL modules and vector implementations.

Table 9	9.3: sundials	direct	linear	solvers	and	matrix	imp.	lement	ations	that	can	be '	used	for	each	n.

The functions within the SUNDIALS-provided SUNLinearSolver implementations return a common set of error codes, shown below in the Table 9.4.

	Table 9.4: Description of the SUNLinearSolver error codes				
Name	Value	Description			
SUNLS_SUCCESS	0	successful call or converged solve			
SUNLS_MEM_NULL	-1	the memory argument to the function is NULL			
SUNLS_ILL_INPUT	-2	an illegal input has been provided to the function			
SUNLS_MEM_FAIL	-3	failed memory access or allocation			
SUNLS_ATIMES_FAIL_UNREC	-4	an unrecoverable failure occurred in the ATimes routine			
SUNLS_PSET_FAIL_UNREC	-5	an unrecoverable failure occurred in the Pset routine			
SUNLS_PSOLVE_FAIL_UNREC	-6	an unrecoverable failure occurred in the Psolve routine			
SUNLS_PACKAGE_FAIL_UNREC	-7	an unrecoverable failure occurred in an external linear solver package			
SUNLS_GS_FAIL	-8	a failure occurred during Gram-Schmidt orthogonalization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)			
SUNLS_QRSOL_FAIL	-9	a singular $R$ matrix was encountered in a QR factorization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)			
SUNLS_RES_REDUCED	1	an iterative solver reduced the residual, but did not converge to the desired tolerance			
SUNLS_CONV_FAIL	2	an iterative solver did not converge (and the residual was not reduced)			
SUNLS_ATIMES_FAIL_REC	3	a recoverable failure occurred in the ATimes routine			
SUNLS_PSET_FAIL_REC	4	a recoverable failure occurred in the Pset routine			
SUNLS_PSOLVE_FAIL_REC	5	a recoverable failure occurred in the Psolve routine			
SUNLS_PACKAGE_FAIL_REC	6	a recoverable failure occurred in an external linear solver package			
SUNLS_QRFACT_FAIL	7	a singular matrix was encountered during a QR factorization (SUNLINSOL_SPGMR/SUNLINSOL_SPFGMR)			
SUNLS_LUFACT_FAIL	8	a singular matrix was encountered during a LU factorization (SUNLINSOL_DENSE/SUNLINSOL_BAND)			

## $9.3 \quad The \ SUNLinear Solver\_Dense \ implementation$

The dense implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_DENSE, is designed to be used with the corresponding SUNMATRIX\_DENSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP or NVECTOR\_PTHREADS). The SUNLINSOL\_DENSE module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Dense {
  sunindextype N;
  sunindextype *pivots;
```

```
long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

**pivots** - index array for partial pivoting in LU factorization,

**last\_flag** - last error return flag from internal function evaluations.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting  $(\mathcal{O}(N^3) \cos t)$ , PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX\_DENSE object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX\_DENSE object  $(\mathcal{O}(N^2) \text{ cost})$ .

The header file to include when using this module is sunlinsol/sunlinsol\_dense.h. The SUNLINSOL\_DENSE module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsoldense module library.

The SUNLINSOL\_DENSE module defines dense implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_Dense
- SUNLinSolInitialize\_Dense this does nothing, since all consistency checks are performed at solver creation.
- SUNLinSolSetup\_Dense this performs the LU factorization.
- SUNLinSolSolve\_Dense this uses the LU factors and pivots array to perform the solve.
- SUNLinSolLastFlag\_Dense
- SUNLinSolSpace\_Dense this only returns information for the storage within the solver object, i.e. storage for N, last\_flag, and pivots.
- SUNLinSolFree\_Dense

The module SUNLINSOL\_DENSE provides the following additional user-callable constructor routine:

#### • SUNDenseLinearSolver

This function creates and allocates memory for a dense SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_DENSE matrix type and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

```
SUNLinearSolver SUNDenseLinearSolver(N_Vector y, SUNMatrix A);
```

For solvers that include a Fortran interface module, the SUNLINSOL\_DENSE module also includes the Fortran-callable function FSUNDenseLinSolInit(code, ier) to initialize this SUNLINSOL\_DENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassDenseLinSolInit(ier) initializes this SUNLINSOL\_DENSE module for solving mass matrix linear systems.

## 9.4 The SUNLinearSolver\_Band implementation

The band implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_BAND, is designed to be used with the corresponding SUNMATRIX\_BAND matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP or NVECTOR\_PTHREADS). The SUNLINSOL\_BAND module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Band {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

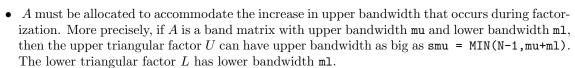

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

**last\_flag** - last error return flag from internal function evaluations.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX\_BAND object A, with pivoting information encoding P stored in the pivots array.
- $\bullet$  The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX\_BAND object.

The header file to include when using this module is sunlinsol/sunlinsol\_band.h. The SUNLINSOL\_BAND module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolband module library.

The SUNLINSOL\_BAND module defines band implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_Band
- SUNLinSolInitialize\_Band this does nothing, since all consistency checks are performed at solver creation.
- SUNLinSolSetup\_Band this performs the *LU* factorization.

- SUNLinSolSolve\_Band this uses the LU factors and pivots array to perform the solve.
- SUNLinSolLastFlag\_Band
- SUNLinSolSpace\_Band this only returns information for the storage within the solver object, i.e. storage for N, last\_flag, and pivots.
- SUNLinSolFree\_Band

The module SUNLINSOL\_BAND provides the following additional user-callable constructor routine:

#### • SUNBandLinearSolver

This function creates and allocates memory for a band SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_BAND matrix type and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

Additionally, this routine will verify that the input matrix A is allocated with appropriate upper bandwidth storage for the LU factorization.

If either A or y are incompatible then this routine will return NULL.

```
SUNLinearSolver SUNBandLinearSolver(N_Vector y, SUNMatrix A);
```

For solvers that include a Fortran interface module, the SUNLINSOL\_BAND module also includes the Fortran-callable function FSUNBandLinSolInit(code, ier) to initialize this SUNLINSOL\_BAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassBandLinSolInit(ier) initializes this SUNLINSOL\_BAND module for solving mass matrix linear systems.

## 9.5 The SUNLinearSolver\_LapackDense implementation

The LAPACK dense implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_LAPACKDENSE, is designed to be used with the corresponding SUNMATRIX\_DENSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP, or NVECTOR\_PTHREADS). The SUNLINSOL\_LAPACKDENSE module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Dense {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

**pivots** - index array for partial pivoting in LU factorization,

**last\_flag** - last error return flag from internal function evaluations.

The SUNLINSOL\_LAPACKDENSE module is a SUNLINSOL wrapper for the LAPACK dense matrix factorization and solve routines, \*GETRF and \*GETRS, where \* is either D or S, depending on whether SUNDIALS was configured to have realtype set to double or single, respectively (see Section 4.2). In order to use the SUNLINSOL\_LAPACKDENSE module it is assumed that LAPACK has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with LAPACK (see Appendix A for details). We note that since there do not exist 128-bit floating-point factorization and solve routines in LAPACK, this interface cannot be compiled when using extended precision for realtype. Similarly, since there do not exist 64-bit integer LAPACK routines, the SUNLINSOL\_LAPACKDENSE module also cannot be compiled when using int64\_t for the sunindextype.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting  $(\mathcal{O}(N^3) \cos t)$ , PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX\_DENSE object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX\_DENSE object  $(\mathcal{O}(N^2) \text{ cost})$ .

The header file to include when using this module is sunlinsol\_lapackdense.h. The installed module library to link to is libsundials\_sunlinsollapackdense. lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL\_LAPACKDENSE module defines dense implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_LapackDense
- SUNLinSolInitialize\_LapackDense this does nothing, since all consistency checks are performed at solver creation.
- ullet SUNLinSolSetup\_LapackDense this calls either DGETRF or SGETRF to perform the LU factorization.
- SUNLinSolSolve\_LapackDense this calls either DGETRS or SGETRS to use the *LU* factors and pivots array to perform the solve.
- SUNLinSolLastFlag\_LapackDense
- SUNLinSolSpace\_LapackDense this only returns information for the storage within the solver object, i.e. storage for N, last\_flag, and pivots.
- SUNLinSolFree\_LapackDense

The module SUNLINSOL\_LAPACKDENSE provides the following additional user-callable constructor routine:

#### • SUNLapackDense

This function creates and allocates memory for a LAPACK dense SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_DENSE matrix type and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNLapackDense(N\_Vector y, SUNMatrix A);

For solvers that include a Fortran interface module, the SUNLINSOL\_LAPACKDENSE module also includes the Fortran-callable function FSUNLapackDenseInit(code, ier) to initialize this SUNLINSOL\_LAPACKDENSE module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassLapackDenseInit(ier) initializes this SUNLINSOL\_LAPACKDENSE module for solving mass matrix linear systems.

## 9.6 The SUNLinearSolver\_LapackBand implementation

The LAPACK band implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_LAPACKBAND, is designed to be used with the corresponding SUNMATRIX\_BAND matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP, or NVECTOR\_PTHREADS). The SUNLINSOL\_LAPACKBAND module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_Band {
   sunindextype N;
   sunindextype *pivots;
   long int last_flag;
};
```

These entries of the *content* field contain the following information:

N - size of the linear system,

pivots - index array for partial pivoting in LU factorization,

**last\_flag** - last error return flag from internal function evaluations.

The SUNLINSOL\_LAPACKBAND module is a SUNLINSOL wrapper for the LAPACK band matrix factorization and solve routines, \*GBTRF and \*GBTRS, where \* is either D or S, depending on whether SUNDIALS was configured to have realtype set to double or single, respectively (see Section 4.2). In order to use the SUNLINSOL\_LAPACKBAND module it is assumed that LAPACK has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with LAPACK (see Appendix A for details). We note that since there do not exist 128-bit floating-point factorization and solve routines in LAPACK, this interface cannot be compiled when using extended precision for realtype. Similarly, since there do not exist 64-bit integer LAPACK routines, the SUNLINSOL\_LAPACKBAND module also cannot be compiled when using int64\_t for the sunindextype.

This solver is constructed to perform the following operations:

- The "setup" call performs a LU factorization with partial (row) pivoting, PA = LU, where P is a permutation matrix, L is a lower triangular matrix with 1's on the diagonal, and U is an upper triangular matrix. This factorization is stored in-place on the input SUNMATRIX\_BAND object A, with pivoting information encoding P stored in the pivots array.
- The "solve" call performs pivoting and forward and backward substitution using the stored pivots array and the LU factors held in the SUNMATRIX\_BAND object.
- A must be allocated to accommodate the increase in upper bandwidth that occurs during factorization. More precisely, if A is a band matrix with upper bandwidth mu and lower bandwidth ml, then the upper triangular factor U can have upper bandwidth as big as smu = MIN(N-1,mu+ml). The lower triangular factor L has lower bandwidth ml.

The header file to include when using this module is sunlinsol\_lapackband.h. The installed module library to link to is libsundials\_sunlinsollapackband. lib where . lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL\_LAPACKBAND module defines band implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_LapackBand
- SUNLinSolInitialize\_LapackBand this does nothing, since all consistency checks are performed at solver creation.
- ullet SUNLinSolSetup\_LapackBand this calls either DGBTRF or SGBTRF to perform the LU factorization.
- SUNLinSolSolve\_LapackBand this calls either DGBTRS or SGBTRS to use the *LU* factors and pivots array to perform the solve.
- SUNLinSolLastFlag\_LapackBand
- SUNLinSolSpace\_LapackBand this only returns information for the storage within the solver object, i.e. storage for N, last\_flag, and pivots.
- SUNLinSolFree\_LapackBand

The module SUNLINSOL\_LAPACKBAND provides the following additional user-callable routine:

#### • SUNLapackBand

This function creates and allocates memory for a LAPACK band SUNLinearSolver. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_BAND matrix type and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

Additionally, this routine will verify that the input matrix  $\mathbf{A}$  is allocated with appropriate upper bandwidth storage for the LU factorization.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNLapackBand(N\_Vector y, SUNMatrix A);

For solvers that include a Fortran interface module, the SUNLINSOL\_LAPACKBAND module also includes the Fortran-callable function FSUNLapackBandInit(code, ier) to initialize this SUNLINSOL\_LAPACKBAND module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassLapackBandInit(ier) initializes this SUNLINSOL\_LAPACKBAND module for solving mass matrix linear systems.

## 9.7 The SUNLinearSolver\_KLU implementation

The KLU implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_KLU, is designed to be used with the corresponding SUNMATRIX\_SPARSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP, or NVECTOR\_PTHREADS). The SUNLINSOL\_KLU module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_KLU {
  long int
                     last_flag;
  int
                     first_factorize;
  sun_klu_symbolic *symbolic;
  sun_klu_numeric *numeric;
  sun_klu_common
                     common;
  sunindextype
                     (*klu_solver)(sun_klu_symbolic*, sun_klu_numeric*,
                                    sunindextype, sunindextype,
                                    double*, sun_klu_common*);
};
These entries of the content field contain the following information:
last_flag - last error return flag from internal function evaluations,
first_factorize - flag indicating whether the factorization has ever been performed,
```

symbolic - KLU storage structure for symbolic factorization components,

**numeric** - KLU storage structure for numeric factorization components,

common - storage structure for common KLU solver components,

klu\_solver - pointer to the appropriate KLU solver function (depending on whether it is using a CSR or CSC sparse matrix).

The SUNLINSOL\_KLU module is a SUNLINSOL wrapper for the KLU sparse matrix factorization and solver library written by Tim Davis [1, 11]. In order to use the SUNLINSOL\_KLU interface to KLU, it is assumed that KLU has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with KLU (see Appendix A for details). Additionally, this wrapper only supports double-precision calculations, and therefore cannot be compiled if SUNDIALS is configured to have realtype set to either extended or single (see Section 4.2). Since the KLU library supports both 32-bit and 64-bit integers, this interface will be compiled for either of the available sunindextype options.

The KLU library has a symbolic factorization routine that computes the permutation of the linear system matrix to block triangular form and the permutations that will pre-order the diagonal blocks (the only ones that need to be factored) to reduce fill-in (using AMD, COLAMD, CHOLAMD, natural, or an ordering given by the user). Of these ordering choices, the default value in the SUNLINSOL\_KLU module is the COLAMD ordering.

KLU breaks the factorization into two separate parts. The first is a symbolic factorization and the second is a numeric factorization that returns the factored matrix along with final pivot information. KLU also has a refactor routine that can be called instead of the numeric factorization. This routine will reuse the pivot information. This routine also returns diagnostic information that a user can examine to determine if numerical stability is being lost and a full numerical factorization should be done instead of the refactor.

Since the linear systems that arise within the context of SUNDIALS calculations will typically have identical sparsity patterns, the SUNLINSOL\_KLU module is constructed to perform the following operations:

- The first time that the "setup" routine is called, it performs the symbolic factorization, followed by an initial numerical factorization.
- On subsequent calls to the "setup" routine, it calls the appropriate KLU "refactor" routine, followed by estimates of the numerical conditioning using the relevant "rcond", and if necessary "condest", routine(s). If these estimates of the condition number are larger than  $\varepsilon^{-2/3}$  (where  $\varepsilon$  is the double-precision unit roundoff), then a new factorization is performed.
- The module includes the routine SUNKLUReInit, that can be called by the user to force a full or partial refactorization at the next "setup" call.

• The "solve" call performs pivoting and forward and backward substitution using the stored KLU data structures. We note that in this solve KLU operates on the native data arrays for the right-hand side and solution vectors, without requiring costly data copies.

The header file to include when using this module is sunlinsol/sunlinsol\_klu.h. The installed module library to link to is libsundials\_sunlinsolklu.lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL\_KLU module defines implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_KLU
- SUNLinSolInitialize\_KLU this sets the first\_factorize flag to 1, forcing both symbolic and numerical factorizations on the subsequent "setup" call.
- SUNLinSolSetup\_KLU this performs either a *LU* factorization or refactorization of the input matrix.
- SUNLinSolSolve\_KLU this calls the appropriate KLU solve routine to utilize the *LU* factors to solve the linear system.
- SUNLinSolLastFlag\_KLU
- SUNLinSolSpace\_KLU this only returns information for the storage within the solver *interface*, i.e. storage for the integers last\_flag and first\_factorize. For additional space requirements, see the KLU documentation.
- SUNLinSolFree\_KLU

The module SUNLINSOL\_KLU provides the following additional user-callable routines:

#### • SUNKLU

This constructor function creates and allocates memory for a SUNLINSOL\_KLU object. Its arguments are an NVECTOR and SUNMATRIX, that it uses to determine the linear system size and to assess compatibility with the linear solver implementation.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_SPARSE matrix type (using either CSR or CSC storage formats) and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL.

SUNLinearSolver SUNKLU(N\_Vector y, SUNMatrix A);

#### • SUNKLUReInit

This function reinitializes memory and flags for a new factorization (symbolic and numeric) to be conducted at the next solver setup call. This routine is useful in the cases where the number of nonzeroes has changed or if the structure of the linear system has changed which would require a new symbolic (and numeric factorization).

The reinit\_type argument governs the level of reinitialization. The allowed values are:

- SUNKLU\_REINIT\_FULL The Jacobian matrix will be destroyed and a new one will be allocated based on the nnz value passed to this call. New symbolic and numeric factorizations will be completed at the next solver setup.
- SUNKLU\_REINIT\_PARTIAL Only symbolic and numeric factorizations will be completed. It is assumed that the Jacobian size has not exceeded the size of nnz given in the sparse matrix provided to the original constructor routine (or the previous SUNKLUReInit call).

This routine assumes no other changes to solver use are necessary.

The return values from this function are SUNLS\_MEM\_NULL (either S or A are NULL), SUNLS\_ILL\_INPUT (A does not have type SUNMATRIX\_SPARSE or reinit\_type is invalid), SUNLS\_MEM\_FAIL (reallocation of the sparse matrix failed) or SUNLS\_SUCCESS.

#### • SUNKLUSetOrdering

This function sets the ordering used by KLU for reducing fill in the linear solve. Options for ordering\_choice are:

- 0 AMD,
- 1 COLAMD, and
- 2 the natural ordering.

The default is 1 for COLAMD.

The return values from this function are SUNLS\_MEM\_NULL (S is NULL), SUNLS\_ILL\_INPUT (invalid ordering\_choice), or SUNLS\_SUCCESS.

```
int SUNKLUSetOrdering(SUNLinearSolver S, int ordering_choice);
```

For solvers that include a Fortran interface module, the SUNLINSOL\_KLU module also includes the Fortran-callable function FSUNKLUInit(code, ier) to initialize this SUNLINSOL\_KLU module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); ier is an error return flag equal to 0 for success and -1 for failure. Both code and ier are declared to match C type int. This routine must be called *after* both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassKLUInit(ier) initializes this SUNLINSOL\_KLU module for solving mass matrix linear systems.

The SUNKLUReInit and SUNKLUSetOrdering routines also support Fortran interfaces for the system and mass matrix solvers:

- FSUNKLUReInit(code, NNZ, reinit\_type, ier) NNZ should be commensurate with a C long int and reinit\_type should be commensurate with a C int (1 = 'FULL', 2 = 'PARTIAL')
- FSUNMassKLUReInit(NNZ, reinit\_type, ier)
- FSUNKLUSetOrdering(code, ordering, ier) ordering should be commensurate with a C int
- FSUNMassKLUSetOrdering(ordering, ier)

## 9.8 The SUNLinearSolver\_SuperLUMT implementation

The SUPERLUMT implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_SUPERLUMT, is designed to be used with the corresponding SUNMATRIX\_SPARSE matrix type, and one of the serial or shared-memory NVECTOR implementations (NVECTOR\_SERIAL, NVECTOR\_OPENMP, or NVECTOR\_PTHREADS). While these are compatible, it is not recommended to use a threaded vector module with SUNLINSOL\_SUPERLUMT unless it is the NVECTOR\_OPENMP module and the SUPERLUMT library has also been compiled with OpenMP. The SUNLINSOL\_SUPERLUMT module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_SuperLUMT {
  long int
                 last_flag;
  int
                 first_factorize;
  SuperMatrix
               *A, *AC, *L, *U, *B;
  Gstat_t
                 *Gstat:
  sunindextype *perm_r, *perm_c;
  sunindextype N;
  int
                num_threads;
                diag_pivot_thresh;
  realtype
  int
                 ordering;
  superlumt_options_t *options;
};
These entries of the content field contain the following information:
last_flag - last error return flag from internal function evaluations,
first_factorize - flag indicating whether the factorization has ever been performed,
A, AC, L, U, B - SuperMatrix pointers used in solve,
Gstat - GStat_t object used in solve,
perm_r, perm_c - permutation arrays used in solve,
N - size of the linear system,
num_threads - number of OpenMP/Pthreads threads to use,
diag_pivot_thresh - threshold on diagonal pivoting,
ordering - flag for which reordering algorithm to use,
options - pointer to SUPERLUMT options structure.
```

The SUNLINSOL\_SUPERLUMT module is a SUNLINSOL wrapper for the SUPERLUMT sparse matrix factorization and solver library written by X. Sherry Li [2, 27, 12]. The package performs matrix factorization using threads to enhance efficiency in shared memory parallel environments. It should be noted that threads are only used in the factorization step. In order to use the SUNLINSOL\_SUPERLUMT interface to SUPERLUMT, it is assumed that SUPERLUMT has been installed on the system prior to installation of SUNDIALS, and that SUNDIALS has been configured appropriately to link with SUPERLUMT (see Appendix A for details). Additionally, this wrapper only supports single- and double-precision calculations, and therefore cannot be compiled if SUNDIALS is configured to have realtype set to extended (see Section 4.2). Moreover, since the SUPERLUMT library may be installed to support either 32-bit or 64-bit integers, it is assumed that the SUPERLUMT library is installed using the same integer precision as the SUNDIALS sunindextype option.

The SUPERLUMT library has a symbolic factorization routine that computes the permutation of the linear system matrix to reduce fill-in on subsequent LU factorizations (using COLAMD, minimal degree ordering on  $A^T * A$ , minimal degree ordering on  $A^T + A$ , or natural ordering). Of these ordering choices, the default value in the SUNLINSOL\_SUPERLUMT module is the COLAMD ordering.

Since the linear systems that arise within the context of SUNDIALS calculations will typically have identical sparsity patterns, the SUNLINSOL\_SUPERLUMT module is constructed to perform the following operations:

- The first time that the "setup" routine is called, it performs the symbolic factorization, followed by an initial numerical factorization.
- On subsequent calls to the "setup" routine, it skips the symbolic factorization, and only refactors the input matrix.

• The "solve" call performs pivoting and forward and backward substitution using the stored SUPERLUMT data structures. We note that in this solve SUPERLUMT operates on the native data arrays for the right-hand side and solution vectors, without requiring costly data copies.

The header file to include when using this module is sunlinsol/sunlinsol\_superlumt.h. The installed module library to link to is libsundials\_sunlinsolsuperlumt.lib where .lib is typically .so for shared libraries and .a for static libraries.

The SUNLINSOL\_SUPERLUMT module defines implementations of all "direct" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_SuperLUMT
- SUNLinSolInitialize\_SuperLUMT this sets the first\_factorize flag to 1 and resets the internal SUPERLUMT statistics variables.
- SUNLinSolSetup\_SuperLUMT this performs either a *LU* factorization or refactorization of the input matrix.
- SUNLinSolSolve\_SuperLUMT this calls the appropriate SUPERLUMT solve routine to utilize the *LU* factors to solve the linear system.
- SUNLinSolLastFlag\_SuperLUMT
- SUNLinSolSpace\_SuperLUMT this only returns information for the storage within the solver *interface*, i.e. storage for the integers last\_flag and first\_factorize. For additional space requirements, see the SUPERLUMT documentation.
- SUNLinSolFree\_SuperLUMT

The module SUNLINSOL\_SUPERLUMT provides the following additional user-callable routines:

#### • SUNSuperLUMT

This constructor function creates and allocates memory for a SUNLINSOL\_SUPERLUMT object. Its arguments are an NVECTOR, a SUNMATRIX, and a desired number of threads (OpenMP or Pthreads, depending on how SUPERLUMT was installed) to use during the factorization steps. This routine analyzes the input matrix and vector to determine the linear system size and to assess compatibility with the SUPERLUMT library.

This routine will perform consistency checks to ensure that it is called with consistent NVECTOR and SUNMATRIX implementations. These are currently limited to the SUNMATRIX\_SPARSE matrix type (using either CSR or CSC storage formats) and the NVECTOR\_SERIAL, NVECTOR\_OPENMP, and NVECTOR\_PTHREADS vector types. As additional compatible matrix and vector implementations are added to SUNDIALS, these will be included within this compatibility check.

If either A or y are incompatible then this routine will return NULL. The num\_threads argument is not checked and is passed directly to SUPERLUMT routines.

SUNLinearSolver SUNSuperLUMT(N\_Vector y, SUNMatrix A, int num\_threads);

#### • SUNSuperLUMTSetOrdering

This function sets the ordering used by SUPERLUMT for reducing fill in the linear solve. Options for ordering\_choice are:

- 0 natural ordering
- 1 minimal degree ordering on  $A^TA$
- 2 minimal degree ordering on  $A^T + A$
- 3 COLAMD ordering for unsymmetric matrices

The default is 3 for COLAMD.

The return values from this function are SUNLS\_MEM\_NULL (S is NULL), SUNLS\_ILL\_INPUT (invalid ordering\_choice), or SUNLS\_SUCCESS.

```
int SUNSuperLUMTSetOrdering(SUNLinearSolver S, int ordering_choice);
```

For solvers that include a Fortran interface module, the SUNLINSOL\_SUPERLUMT module also includes the Fortran-callable function FSUNSuperLUMTInit(code, num\_threads, ier) to initialize this SUNLINSOL\_SUPERLUMT module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); num\_threads is the desired number of Open-MP/Pthreads threads to use in the factorization; ier is an error return flag equal to 0 for success and -1 for failure. All of these arguments should be declared so as to match C type int. This routine must be called after both the NVECTOR and SUNMATRIX objects have been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSuperLUMTInit(num\_threads, ier) initializes this SUNLINSOL\_SUPERLUMT module for solving mass matrix linear systems.

The SUNSuperLUMTSetOrdering routine also supports Fortran interfaces for the system and mass matrix solvers:

- FSUNSuperLUMTSetOrdering(code, ordering, ier) ordering should be commensurate with a C int
- FSUNMassSuperLUMTSetOrdering(ordering, ier)

### 9.9 The SUNLinearSolver\_SPGMR implementation

The SPGMR (Scaled, Preconditioned, Generalized Minimum Residual [33]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_SPGMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N\_VClone, N\_VDotProd, N\_VScale, N\_VLinearSum, N\_VProd, N\_VConst, N\_VDiv, and N\_VDestroy).

The  $\mathtt{SUNLINSOL\_SPGMR}$  module defines the content field of a  $\mathtt{SUNLinearSolver}$  to be the following structure:

```
struct _SUNLinearSolverContent_SPGMR {
  int maxl;
  int pretype;
  int gstype;
  int max_restarts;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector *V;
  realtype **Hes;
  realtype *givens;
  N_Vector xcor;
  realtype *yg;
  N_Vector vtemp;
};
```

These entries of the *content* field contain the following information:

maxl - number of GMRES basis vectors to use (default is 5),

**pretype** - flag for type of preconditioning to employ (default is none),

gstype - flag for type of Gram-Schmidt orthogonalization (default is modified Gram-Schmidt),

max\_restarts - number of GMRES restarts to allow (default is 0),

numiters - number of iterations from the most-recent solve,

resnorm - final linear residual norm from the most-recent solve,

last\_flag - last error return flag from an internal function,

**ATimes** - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

**Psolve** - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

**V** - the array of Krylov basis vectors  $v_1, \ldots, v_{\mathtt{maxl}+1}$ , stored in  $V[0], \ldots, V[\mathtt{maxl}]$ . Each  $v_i$  is a vector of type NVECTOR.,

Hes - the  $(\max 1 + 1) \times \max 1$  Hessenberg matrix. It is stored row-wise so that the (i,j)th element is given by Hes[i][j].,

givens - a length 2\*maxl array which represents the Givens rotation matrices that arise in the GMRES

algorithm. These matrices are 
$$F_0, F_1, \ldots, F_j$$
, where  $F_i = \begin{bmatrix} 1 & & & & \\ & \ddots & & \\ & & 1 & & \\ & & c_i & -s_i & \\ & & s_i & c_i & \\ & & & 1 & \\ & & & \ddots & \\ & & & & 1 \end{bmatrix}$  are represented in the givens vector as givens [0] =  $c_0$ , givens [1] =  $s_0$ , givens [2] =  $c_1$ ,

xcor - a vector which holds the scaled, preconditioned correction to the initial guess,

givens[3] =  $s_1, \dots$  givens[2j] =  $c_j$ , givens[2j+1] =  $s_j$ .

yg - a length (maxl+1) array of realtype values used to hold "short" vectors (e.g. y and g),

vtemp - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction, the xcor and vtemp arrays are cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL\_SPGMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.

- In the "initialize" call, the remaining solver data is allocated (V, Hes, givens, and yg)
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call, the GMRES iteration is performed. This will include scaling, preconditioning, and restarts if those options have been supplied.

The header file to include when using this module is sunlinsol\_spgmr.h. The SUNLIN-SOL\_SPGMR module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolspgmr module library.

The SUNLINSOL\_SPGMR module defines implementations of all "iterative" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_SPGMR
- SUNLinSolInitialize\_SPGMR
- SUNLinSolSetATimes\_SPGMR
- SUNLinSolSetPreconditioner\_SPGMR
- SUNLinSolSetScalingVectors\_SPGMR
- SUNLinSolSetup\_SPGMR
- SUNLinSolSolve\_SPGMR
- SUNLinSolNumIters\_SPGMR
- SUNLinSolResNorm\_SPGMR
- SUNLinSolResid\_SPGMR
- SUNLinSolLastFlag\_SPGMR
- SUNLinSolSpace\_SPGMR
- SUNLinSolFree\_SPGMR

The module SUNLINSOL\_SPGMR provides the following additional user-callable routines:

#### • SUNSPGMR

This constructor function creates and allocates memory for a SPGMR SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of Krylov basis vectors to use.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is  $\leq 0$  will result in the default value (5).

Allowable inputs for pretype are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2) and PREC\_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL\_SPGMR object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPGMR(N\_Vector y, int pretype, int maxl);

#### • SUNSPGMRSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2) and PREC\_BOTH (3).

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal pretype), SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS.

int SUNSPGMRSetPrecType(SUNLinearSolver S, int pretype);

#### • SUNSPGMRSetGSType

This function sets the type of Gram-Schmidt orthogonalization to use. Supported values are MODIFIED\_GS (1) and CLASSICAL\_GS (2). Any other integer input will result in a failure, returning error code SUNLS\_ILL\_INPUT.

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal gstype), SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS.

int SUNSPGMRSetGSType(SUNLinearSolver S, int gstype);

#### • SUNSPGMRSetMaxRestarts

This function sets the number of GMRES restarts to allow. A negative input will result in the default of 0.

This routine will return with one of the error codes SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS. int SUNSPGMRSetMaxRestarts(SUNLinearSolver S, int maxrs);

For solvers that include a Fortran interface module, the SUNLINSOL\_SPGMR module also includes the Fortran-callable function FSUNSPGMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL\_SPGMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPGMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPGMRInit(pretype, maxl, ier) initializes this SUNLINSOL\_SPGMR module for solving mass matrix linear systems.

The SUNSPGMRSetPrecType, SUNSPGMRSetGSType and SUNSPGMRSetMaxRestarts routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

- FSUNSPGMRSetGSType(code, gstype, ier)
- FSUNMassSPGMRSetGSType(gstype, ier)
- FSUNSPGMRSetPrecType(code, pretype, ier)
- FSUNMassSPGMRSetPrecType(pretype, ier)
- FSUNSPGMRSetMaxRS(code, maxrs, ier)
- FSUNMassSPGMRSetMaxRS(maxrs, ier)

## 9.10 The SUNLinearSolver\_SPFGMR implementation

The SPFGMR (Scaled, Preconditioned, Flexible, Generalized Minimum Residual [32]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_SPFGMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N\_VClone, N\_VDotProd, N\_VScale, N\_VLinearSum, N\_VProd, N\_VConst, N\_VDiv, and N\_VDestroy). Unlike the other Krylov iterative linear

solvers supplied with SUNDIALS, FGMRES is specifically designed to work with a changing preconditioner (e.g. from an iterative method).

The SUNLINSOL\_SPFGMR module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_SPFGMR {
  int maxl;
  int pretype;
  int gstype;
  int max_restarts;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector *V;
  N_Vector *Z;
  realtype **Hes;
  realtype *givens;
  N_Vector xcor;
  realtype *yg;
  N_Vector vtemp;
These entries of the content field contain the following information:
maxl - number of FGMRES basis vectors to use (default is 5),
pretype - flag for use of preconditioning (default is none),
gstype - flag for type of Gram-Schmidt orthogonalization (default is modified Gram-Schmidt),
max_restarts - number of FGMRES restarts to allow (default is 0),
numiters - number of iterations from the most-recent solve,
resnorm - final linear residual norm from the most-recent solve,
last_flag - last error return flag from an internal function,
ATimes - function pointer to perform Av product,
ATData - pointer to structure for ATimes,
Psetup - function pointer to preconditioner setup routine,
Psolve - function pointer to preconditioner solve routine,
PData - pointer to structure for Psetup and Psolve,
s1, s2 - vector pointers for supplied scaling matrices (default is NULL),
\mathbf V - the array of Krylov basis vectors v_1, \ldots, v_{\mathtt{maxl+1}}, stored in \mathtt V[\mathtt 0], \ldots, \mathtt V[\mathtt{maxl}]. Each v_i is a vector
     of type NVECTOR.,
```

**Z** - the array of preconditioned Krylov basis vectors  $z_1, \ldots, z_{\texttt{maxl}+1}$ , stored in Z[0], ..., Z[maxl]. Each  $z_i$  is a vector of type NVECTOR.,

**Hes** - the  $(\max 1 + 1) \times \max 1$  Hessenberg matrix. It is stored row-wise so that the (i,j)th element is given by Hes[i][j].

givens - a length 2\*maxl array which represents the Givens rotation matrices that arise in the FGM-

are represented in the givens vector as givens  $[0] = c_0$ , givens  $[1] = s_0$ , givens  $[2] = c_1$ , givens  $[3] = s_1$ , ... givens  $[2j] = c_j$ , givens  $[2j+1] = s_j$ .

xcor - a vector which holds the scaled, preconditioned correction to the initial guess,

yg - a length (maxl+1) array of realtype values used to hold "short" vectors (e.g. y and g),

vtemp - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction, the xcor and vtemp arrays are cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL\_SPFGMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the remaining solver data is allocated (V, Hes, givens, and vg)
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call, the FGMRES iteration is performed. This will include scaling, preconditioning, and restarts if those options have been supplied.

The header file to include when using this module is sunlinsol/sunlinsol\_spfgmr.h. The SUNLIN-SOL\_SPFGMR module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolspfgmr module library.

The SUNLINSOL\_SPFGMR module defines implementations of all "iterative" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_SPFGMR
- SUNLinSolInitialize\_SPFGMR
- SUNLinSolSetATimes\_SPFGMR
- SUNLinSolSetPreconditioner\_SPFGMR
- $\bullet \ \, {\tt SUNLinSolSetScalingVectors\_SPFGMR}$
- SUNLinSolSetup\_SPFGMR

- SUNLinSolSolve\_SPFGMR
- SUNLinSolNumIters\_SPFGMR
- SUNLinSolResNorm\_SPFGMR
- SUNLinSolResid\_SPFGMR
- SUNLinSolLastFlag\_SPFGMR
- SUNLinSolSpace\_SPFGMR
- SUNLinSolFree\_SPFGMR

The module SUNLINSOL\_SPFGMR provides the following additional user-callable routines:

#### • SUNSPFGMR

This constructor function creates and allocates memory for a SPFGMR SUNLinearSolver. Its arguments are an NVECTOR, a flag indicating to use preconditioning, and the number of Krylov basis vectors to use.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is  $\leq 0$  will result in the default value (5).

Since the FGMRES algorithm is designed to only support right preconditioning, then any of the pretype inputs PREC\_LEFT (1), PREC\_RIGHT (2), or PREC\_BOTH (3) will result in use of PREC\_RIGHT; any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS). While it is possible to use a right-preconditioned SUNLINSOL\_SPFGMR object for these packages, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPFGMR(N\_Vector y, int pretype, int maxl);

#### • SUNSPFGMRSetPrecType

This function updates the flag indicating use of preconditioning. Since the FGMRES algorithm is designed to only support right preconditioning, then any of the pretype inputs PREC\_LEFT (1), PREC\_RIGHT (2), or PREC\_BOTH (3) will result in use of PREC\_RIGHT; any other integer input will result in the default (no preconditioning).

This routine will return with one of the error codes SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS. int SUNSPFGMRSetPrecType(SUNLinearSolver S, int pretype);

#### • SUNSPFGMRSetGSType

This function sets the type of Gram-Schmidt orthogonalization to use. Supported values are MODIFIED\_GS (1) and CLASSICAL\_GS (2). Any other integer input will result in a failure, returning error code SUNLS\_ILL\_INPUT.

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal gstype), SUNLS\_MEM\_NULL (S is NULL), or SUNLS\_SUCCESS.

int SUNSPFGMRSetGSType(SUNLinearSolver S, int gstype);

#### • SUNSPFGMRSetMaxRestarts

This function sets the number of FGMRES restarts to allow. A negative input will result in the default of 0.

This routine will return with one of the error codes SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS.

int SUNSPFGMRSetMaxRestarts(SUNLinearSolver S, int maxrs);

For solvers that include a Fortran interface module, the SUNLINSOL\_SPFGMR module also includes the Fortran-callable function FSUNSPFGMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL\_SPFGMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPFGMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPFGMRInit(pretype, maxl, ier) initializes this SUNLINSOL\_SPFGMR module for solving mass matrix linear systems.

The SUNSPFGMRSetPrecType, SUNSPFGMRSetGSType, and SUNSPFGMRSetMaxRestarts routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

```
FSUNSPFGMRSetGSType(code, gstype, ier)
FSUNMassSPFGMRSetGSType(gstype, ier)
FSUNSPFGMRSetPrecType(code, pretype, ier)
FSUNMassSPFGMRSetPrecType(pretype, ier)
FSUNSPFGMRSetMaxRS(code, maxrs, ier)
```

• FSUNMassSPFGMRSetMaxRS(maxrs, ier)

## 9.11 The SUNLinearSolver\_SPBCGS implementation

The SPBCGS (Scaled, Preconditioned, Bi-Conjugate Gradient, Stabilized [36]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_SPBCGS, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N\_VClone, N\_VDotProd, N\_VScale, N\_VLinearSum, N\_VProd, N\_VDiv, and N\_VDestroy). Unlike the SPGMR and SPFGMR algorithms, SPBCGS requires a fixed amount of memory that does not increase with the number of allowed iterations.

The  $\mathtt{SUNLINSOL\_SPBCGS}$  module defines the content field of a  $\mathtt{SUNLinearSolver}$  to be the following structure:

```
struct _SUNLinearSolverContent_SPBCGS {
  int maxl;
  int pretype;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector r;
  N_Vector r_star;
  N_Vector p;
  N_Vector q;
  N_Vector u;
  N_Vector Ap;
  N_Vector vtemp;
};
```

These entries of the *content* field contain the following information:

maxl - number of SPBCGS iterations to allow (default is 5),

**pretype** - flag for type of preconditioning to employ (default is none),

numiters - number of iterations from the most-recent solve,

resnorm - final linear residual norm from the most-recent solve,

last\_flag - last error return flag from an internal function,

**ATimes** - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

Psolve - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

r - a NVECTOR which holds the current scaled, preconditioned linear system residual,

r\_star - a NVECTOR which holds the initial scaled, preconditioned linear system residual,

p, q, u, Ap, vtemp - NVECTORS used for workspace by the SPBCGS algorithm.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL\_SPBCGS to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the SPBCGS iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol\_spbcgs.h. The SUNLINSOL\_SPBCGS module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolspbcgs module library.

The SUNLINSOL\_SPBCGS module defines implementations of all "iterative" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_SPBCGS
- SUNLinSolInitialize\_SPBCGS
- SUNLinSolSetATimes\_SPBCGS
- SUNLinSolSetPreconditioner\_SPBCGS
- SUNLinSolSetScalingVectors\_SPBCGS

- SUNLinSolSetup\_SPBCGS
- SUNLinSolSolve\_SPBCGS
- SUNLinSolNumIters\_SPBCGS
- SUNLinSolResNorm\_SPBCGS
- SUNLinSolResid\_SPBCGS
- SUNLinSolLastFlag\_SPBCGS
- SUNLinSolSpace\_SPBCGS
- SUNLinSolFree\_SPBCGS

The module SUNLINSOL\_SPBCGS provides the following additional user-callable routines:

#### • SUNSPBCGS

This constructor function creates and allocates memory for a SPBCGS SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is  $\leq 0$  will result in the default value (5).

Allowable inputs for pretype are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2) and PREC\_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL\_SPBCGS object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPBCGS(N\_Vector y, int pretype, int maxl);

#### • SUNSPBCGSSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2), and PREC\_BOTH (3).

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal pretype), SUNLS\_MEM\_NULL (S is NULL), or SUNLS\_SUCCESS.

int SUNSPBCGSSetPrecType(SUNLinearSolver S, int pretype);

#### • SUNSPBCGSSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is  $\leq 0$  will result in the default value (5).

This routine will return with one of the error codes SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS.

int SUNSPBCGSSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL\_SPBCGS module also includes the Fortran-callable function FSUNSPBCGSInit(code, pretype, maxl, ier) to initialize this SUNLINSOL\_SPBCGS module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPBCGS; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity

mass matrix, the Fortran-callable function FSUNMassSPBCGSInit(pretype, maxl, ier) initializes this SUNLINSOL\_SPBCGS module for solving mass matrix linear systems.

The SUNSPBCGSSetPrecType and SUNSPBCGSSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

```
• FSUNSPBCGSSetPrecType(code, pretype, ier)
```

- FSUNMassSPBCGSSetPrecType(pretype, ier)
- FSUNSPBCGSSetMaxl(code, maxl, ier)
- FSUNMassSPBCGSSetMaxl(maxl, ier)

struct \_SUNLinearSolverContent\_SPTFQMR {

## 9.12 The SUNLinearSolver\_SPTFQMR implementation

The SPTFQMR (Scaled, Preconditioned, Transpose-Free Quasi-Minimum Residual [14]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_SPTFQMR, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N\_VClone, N\_VDotProd, N\_VScale, N\_VLinearSum, N\_VProd, N\_VConst, N\_VDiv, and N\_VDestroy). Unlike the SPGMR and SPFGMR algorithms, SPTFQMR requires a fixed amount of memory that does not increase with the number of allowed iterations.

The SUNLINSOL\_SPTFQMR module defines the *content* field of a SUNLinearSolver to be the following structure:

```
int maxl;
  int pretype;
  int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s1;
  N_Vector s2;
  N_Vector r_star;
  N_Vector q;
  N_Vector d;
  N_Vector v;
  N_Vector p;
  N_Vector *r;
  N_Vector u;
  N_Vector vtemp1;
  N_Vector vtemp2;
  N_Vector vtemp3;
};
These entries of the content field contain the following information:
maxl - number of TFQMR iterations to allow (default is 5),
pretype - flag for type of preconditioning to employ (default is none),
numiters - number of iterations from the most-recent solve,
```

resnorm - final linear residual norm from the most-recent solve,

last\_flag - last error return flag from an internal function,

**ATimes** - function pointer to perform Av product,

ATData - pointer to structure for ATimes,

Psetup - function pointer to preconditioner setup routine,

Psolve - function pointer to preconditioner solve routine,

PData - pointer to structure for Psetup and Psolve,

s1, s2 - vector pointers for supplied scaling matrices (default is NULL),

r\_star - a NVECTOR which holds the initial scaled, preconditioned linear system residual,

q, d, v, p, u - NVECTORS used for workspace by the SPTFQMR algorithm,

r - array of two NVECTORS used for workspace within the SPTFQMR algorithm,

vtemp1, vtemp2, vtemp3 - temporary vector storage.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL\_SPTFQMR to supply the ATimes, PSetup, and Psolve function pointers and s1 and s2 scaling vectors.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the TFQMR iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol/sunlinsol\_sptfqmr.h. The SUNLINSOL\_SPTFQMR module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolsptfqmr module library.

The SUNLINSOL\_SPTFQMR module defines implementations of all "iterative" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_SPTFQMR
- SUNLinSolInitialize\_SPTFQMR
- SUNLinSolSetATimes\_SPTFQMR
- SUNLinSolSetPreconditioner\_SPTFQMR
- SUNLinSolSetScalingVectors\_SPTFQMR
- SUNLinSolSetup\_SPTFQMR
- $\bullet \ {\tt SUNLinSolSolve\_SPTFQMR} \\$
- SUNLinSolNumIters\_SPTFQMR

- SUNLinSolResNorm\_SPTFQMR
- SUNLinSolResid\_SPTFQMR
- SUNLinSolLastFlag\_SPTFQMR
- SUNLinSolSpace\_SPTFQMR
- SUNLinSolFree\_SPTFQMR

The module SUNLINSOL\_SPTFQMR provides the following additional user-callable routines:

#### • SUNSPTFQMR

This constructor function creates and allocates memory for a SPTFQMR SUNLinearSolver. Its arguments are an NVECTOR, the desired type of preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible, then this routine will return NULL.

A max1 argument that is  $\leq 0$  will result in the default value (5).

Allowable inputs for pretype are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2) and PREC\_BOTH (3); any other integer input will result in the default (no preconditioning). We note that some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL). While it is possible to configure a SUNLINSOL\_SPTFQMR object to use any of the preconditioning options with these solvers, this use mode is not supported and may result in inferior performance.

SUNLinearSolver SUNSPTFQMR(N\_Vector y, int pretype, int maxl);

#### • SUNSPTFQMRSetPrecType

This function updates the type of preconditioning to use. Supported values are PREC\_NONE (0), PREC\_LEFT (1), PREC\_RIGHT (2), and PREC\_BOTH (3).

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal pretype), SUNLS\_MEM\_NULL (S is NULL), or SUNLS\_SUCCESS.

int SUNSPTFQMRSetPrecType(SUNLinearSolver S, int pretype);

#### • SUNSPTFQMRSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is  $\leq 0$  will result in the default value (5).

This routine will return with one of the error codes  ${\tt SUNLS\_MEM\_NULL} \ ({\tt S} \ {\tt is} \ {\tt NULL}) \ {\tt or} \ {\tt SUNLS\_SUCCESS}.$ 

int SUNSPTFQMRSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL\_SPTFQMR module also includes the Fortran-callable function FSUNSPTFQMRInit(code, pretype, maxl, ier) to initialize this SUNLINSOL\_SPTFQMR module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNSPTFQMR; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassSPTFQMRInit(pretype, maxl, ier) initializes this SUNLINSOL\_SPTFQMR module for solving mass matrix linear systems.

The SUNSPTFQMRSetPrecType and SUNSPTFQMRSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

• FSUNSPTFQMRSetPrecType(code, pretype, ier)

- FSUNMassSPTFQMRSetPrecType(pretype, ier)
- FSUNSPTFQMRSetMaxl(code, maxl, ier)
- FSUNMassSPTFQMRSetMaxl(maxl, ier)

## 9.13 The SUNLinearSolver\_PCG implementation

The PCG (Preconditioned Conjugate Gradient [15]) implementation of the SUNLINSOL module provided with SUNDIALS, SUNLINSOL\_PCG, is an iterative linear solver that is designed to be compatible with any NVECTOR implementation (serial, threaded, parallel, and user-supplied) that supports a minimal subset of operations (N\_VClone, N\_VDotProd, N\_VScale, N\_VLinearSum, N\_VProd, and N\_VDestroy). Unlike the SPGMR and SPFGMR algorithms, PCG requires a fixed amount of memory that does not increase with the number of allowed iterations.

Unlike all of the other iterative linear solvers supplied with Sundials, PCG should only be used on symmetric linear systems (e.g. mass matrix linear systems encountered in ARKODE). As a result, the explanation of the role of scaling and preconditioning matrices given in general must be modified in this scenario. The PCG algorithm solves a linear system Ax = b where A is a symmetric ( $A^T = A$ ), real-valued matrix. Preconditioning is allowed, and is applied in a symmetric fashion on both the right and left. Scaling is also allowed and is applied symmetrically. We denote the preconditioner and scaling matrices as follows:

- P is the preconditioner (assumed symmetric),
- $\bullet$  S is a diagonal matrix of scale factors.

The matrices A and P are not required explicitly; only routines that provide A and  $P^{-1}$  as operators are required. The diagonal of the matrix S is held in a single NVECTOR, supplied by the user.

In this notation, PCG applies the underlying CG algorithm to the equivalent transformed system

$$\tilde{A}\tilde{x} = \tilde{b} \tag{9.3}$$

where

$$\tilde{A} = SP^{-1}AP^{-1}S,$$

$$\tilde{b} = SP^{-1}b,$$

$$\tilde{x} = S^{-1}Px.$$

$$(9.4)$$

The scaling matrix must be chosen so that the vectors  $SP^{-1}b$  and  $S^{-1}Px$  have dimensionless components.

The stopping test for the PCG iterations is on the L2 norm of the scaled preconditioned residual:

$$\begin{split} &\|\tilde{b} - \tilde{A}\tilde{x}\|_2 < \delta \\ \Leftrightarrow & \\ &\|SP^{-1}b - SP^{-1}Ax\|_2 < \delta \\ \Leftrightarrow & \\ &\|P^{-1}b - P^{-1}Ax\|_S < \delta \end{split}$$

where  $||v||_S = \sqrt{v^T S^T S v}$ , with an input tolerance  $\delta$ .

The SUNLINSOL\_PCG module defines the *content* field of a SUNLinearSolver to be the following structure:

```
struct _SUNLinearSolverContent_PCG {
  int maxl;
  int pretype;
```

```
int numiters;
  realtype resnorm;
  long int last_flag;
  ATimesFn ATimes;
  void* ATData;
  PSetupFn Psetup;
  PSolveFn Psolve;
  void* PData;
  N_Vector s;
  N_Vector r;
  N_Vector p;
  N_Vector z;
  N_Vector Ap;
};
These entries of the content field contain the following information:
maxl - number of PCG iterations to allow (default is 5),
pretype - flag for use of preconditioning (default is none),
numiters - number of iterations from the most-recent solve,
resnorm - final linear residual norm from the most-recent solve.
last_flag - last error return flag from an internal function,
ATimes - function pointer to perform Av product,
ATData - pointer to structure for ATimes,
Psetup - function pointer to preconditioner setup routine,
Psolve - function pointer to preconditioner solve routine,
PData - pointer to structure for Psetup and Psolve,
s - vector pointer for supplied scaling matrix (default is NULL),
r - a NVECTOR which holds the preconditioned linear system residual,
```

p, z, Ap - NVECTORS used for workspace by the PCG algorithm.

This solver is constructed to perform the following operations:

- During construction all NVECTOR solver data is allocated, with vectors cloned from a template NVECTOR that is input, and default solver parameters are set.
- User-facing "set" routines may be called to modify default solver parameters.
- Additional "set" routines are called by the SUNDIALS solver that interfaces with SUNLINSOL\_PCG to supply the ATimes, PSetup, and Psolve function pointers and s scaling vector.
- In the "initialize" call, the solver parameters are checked for validity.
- In the "setup" call, any non-NULL PSetup function is called. Typically, this is provided by the SUNDIALS solver itself, that translates between the generic PSetup function and the solver-specific routine (solver-supplied or user-supplied).
- In the "solve" call the PCG iteration is performed. This will include scaling and preconditioning if those options have been supplied.

The header file to include when using this module is sunlinsol\_pcg.h. The SUNLIN-SOL\_PCG module is accessible from all SUNDIALS solvers without linking to the

libsundials\_sunlinsolpcg module library.

The SUNLINSOL\_PCG module defines implementations of all "iterative" linear solver operations listed in Table 9.2:

- SUNLinSolGetType\_PCG
- SUNLinSolInitialize\_PCG
- SUNLinSolSetATimes\_PCG
- SUNLinSolSetPreconditioner\_PCG
- SUNLinSolSetScalingVectors\_PCG since PCG only supports symmetric scaling, the second NVECTOR argument to this function is ignored
- SUNLinSolSetup\_PCG
- SUNLinSolSolve\_PCG
- SUNLinSolNumIters\_PCG
- SUNLinSolResNorm\_PCG
- SUNLinSolResid\_PCG
- SUNLinSolLastFlag\_PCG
- SUNLinSolSpace\_PCG
- SUNLinSolFree\_PCG

The module SUNLINSOL\_PCG provides the following additional user-callable routines:

#### • SUNPCG

This constructor function creates and allocates memory for a PCG SUNLinearSolver. Its arguments are an NVECTOR, a flag indicating to use preconditioning, and the number of linear iterations to allow.

This routine will perform consistency checks to ensure that it is called with a consistent NVECTOR implementation (i.e. that it supplies the requisite vector operations). If y is incompatible then this routine will return NULL.

A max1 argument that is  $\leq 0$  will result in the default value (5).

Since the PCG algorithm is designed to only support symmetric preconditioning, then any of the pretype inputs PREC\_LEFT (1), PREC\_RIGHT (2), or PREC\_BOTH (3) will result in use of the symmetric preconditioner; any other integer input will result in the default (no preconditioning). Although some SUNDIALS solvers are designed to only work with left preconditioning (IDA and IDAS) and others with only right preconditioning (KINSOL), PCG should *only* be used with these packages when the linear systems are known to be *symmetric*. Since the scaling of matrix rows and columns must be identical in a symmetric matrix, symmetric preconditioning should work appropriately even for packages designed with one-sided preconditioning in mind.

SUNLinearSolver SUNPCG(N\_Vector y, int pretype, int maxl);

#### • SUNPCGSetPrecType

This function updates the flag indicating use of preconditioning. As above, any one of the input values, PREC\_LEFT (1), PREC\_RIGHT (2), or PREC\_BOTH (3) will enable preconditioning; PREC\_NONE (0) disables preconditioning.

This routine will return with one of the error codes SUNLS\_ILL\_INPUT (illegal pretype), SUNLS\_MEM\_NULL (S is NULL), or SUNLS\_SUCCESS.

int SUNPCGSetPrecType(SUNLinearSolver S, int pretype);

#### • SUNPCGSetMax1

This function updates the number of linear solver iterations to allow.

A max1 argument that is  $\leq 0$  will result in the default value (5).

This routine will return with one of the error codes SUNLS\_MEM\_NULL (S is NULL) or SUNLS\_SUCCESS. int SUNPCGSetMaxl(SUNLinearSolver S, int maxl);

For solvers that include a Fortran interface module, the SUNLINSOL\_PCG module also includes the Fortran-callable function FSUNPCGInit(code, pretype, maxl, ier) to initialize this SUNLINSOL\_PCG module for a given SUNDIALS solver. Here code is an integer input solver id (1 for CVODE, 2 for IDA, 3 for KINSOL, 4 for ARKODE); pretype and maxl are the same as for the C function SUNPCG; ier is an error return flag equal to 0 for success and -1 for failure. All of these input arguments should be declared so as to match C type int. This routine must be called after the NVECTOR object has been initialized. Additionally, when using ARKODE with a non-identity mass matrix, the Fortran-callable function FSUNMassPCGInit(pretype, maxl, ier) initializes this SUNLINSOL\_PCG module for solving mass matrix linear systems.

The SUNPCGSetPrecType and SUNPCGSetMaxl routines also support Fortran interfaces for the system and mass matrix solvers (all arguments should be commensurate with a C int):

- FSUNPCGSetPrecType(code, pretype, ier)
- FSUNMassPCGSetPrecType(pretype, ier)
- FSUNPCGSetMaxl(code, maxl, ier)
- FSUNMassPCGSetMaxl(maxl, ier)

## 9.14 SUNLinearSolver Examples

There are SUNLinearSolver examples that may be installed for each implementation; these make use of the functions in test\_sunlinsol.c. These example functions show simple usage of the SUNLinearSolver family of functions. The inputs to the examples depend on the linear solver type, and are output to stdout if the example is run without the appropriate number of command-line arguments.

The following is a list of the example functions in test\_sunlinsol.c:

- Test\_SUNLinSolGetType: Verifies the returned solver type against the value that should be returned.
- Test\_SUNLinSolInitialize: Verifies that SUNLinSolInitialize can be called and returns successfully.
- Test\_SUNLinSolSetup: Verifies that SUNLinSolSetup can be called and returns successfully.
- Test\_SUNLinSolSolve: Given a SUNMATRIX object A, NVECTOR objects x and b (where Ax = b) and a desired solution tolerance tol, this routine clones x into a new vector y, calls SUNLinSolSolve to fill y as the solution to Ay = b (to the input tolerance), verifies that each entry in x and y match to within 10\*tol, and overwrites x with y prior to returning (in case the calling routine would like to investigate further).
- Test\_SUNLinSolSetATimes (iterative solvers only): Verifies that SUNLinSolSetATimes can be called and returns successfully.
- Test\_SUNLinSolSetPreconditioner (iterative solvers only): Verifies that SUNLinSolSetPreconditioner can be called and returns successfully.
- Test\_SUNLinSolSetScalingVectors (iterative solvers only): Verifies that SUNLinSolSetScalingVectors can be called and returns successfully.

- Test\_SUNLinSolLastFlag: Verifies that SUNLinSolLastFlag can be called, and outputs the result to stdout.
- Test\_SUNLinSolNumIters (iterative solvers only): Verifies that SUNLinSolNumIters can be called, and outputs the result to stdout.
- Test\_SUNLinSolResNorm (iterative solvers only): Verifies that SUNLinSolResNorm can be called, and that the result is non-negative.
- Test\_SUNLinSolResid (iterative solvers only): Verifies that SUNLinSolResid can be called.
- Test\_SUNLinSolSpace verifies that SUNLinSolSpace can be called, and outputs the results to stdout.

We'll note that these tests should be performed in a particular order. For either direct or iterative linear solvers, Test\_SUNLinSolInitialize must be called before Test\_SUNLinSolSetup, which must be called before Test\_SUNLinSolSolve. Additionally, for iterative linear solvers Test\_SUNLinSolSetATimes, Test\_SUNLinSolSetPreconditioner and Test\_SUNLinSolSetScalingVectors should be called before Test\_SUNLinSolInitialize; similarly Test\_SUNLinSolNumIters, Test\_SUNLinSolResNorm and Test\_SUNLinSolResid should be called after Test\_SUNLinSolSolve. These are called in the appropriate order in all of the example problems.

## 9.15 SUNLinearSolver functions used by CVODES

In Table 9.5 below, we list the linear solver functions in the SUNLINSOL module used within the CVODES package. The table also shows, for each function, which of the code modules uses the function. In general, the main CVODES integrator considers three categories of linear solvers, direct, iterative and custom, with interfaces accessible in the CVODES header files cvodes\_direct.h (CVDLS), cvodes\_spils.h (CVSPILS) and cvodes\_customls.h (CVCLS), respectively. Hence, the table columns reference the use of SUNLINSOL functions by each of these solver interfaces.

As with the SUNMATRIX module, we emphasize that the CVODES user does not need to know detailed usage of linear solver functions by the CVODES code modules in order to use CVODES. The information is presented as an implementation detail for the interested reader.

	CVDLS	CVSPILS	CVCLS
SUNLinSolGetType	<b>√</b>	<b>√</b>	†
SUNLinSolSetATimes		<b>√</b>	†
SUNLinSolSetPreconditioner		<b>√</b>	†
SUNLinSolSetScalingVectors		<b>√</b>	†
SUNLinSolInitialize	<b>√</b>	<b>√</b>	<b>√</b>
SUNLinSolSetup	<b>√</b>	<b>√</b>	<b>√</b>
SUNLinSolSolve	<b>√</b>	<b>√</b>	<b>√</b>
SUNLinSolNumIters		<b>√</b>	†
SUNLinSolResNorm		<b>√</b>	†
SUNLinSolResid		<b>√</b>	†
SUNLinSolLastFlag			
SUNLinSolFree	<b>√</b>	<b>√</b>	<b>√</b>
SUNLinSolSpace	†	†	†

Table 9.5: List of linear solver functions usage by CVODES code modules

The linear solver functions listed in Table 9.2 with a † symbol are optionally used, in that these are only called if they are implemented in the SUNLINSOL module that is being used (i.e. their function

pointers are non-NULL). Also, although CVODES does not call the SUNLinSolLastFlag directly, this routine is available for users to query linear solver issues directly.

## Appendix A

## SUNDIALS Package Installation Procedure

The installation of any SUNDIALS package is accomplished by installing the SUNDIALS suite as a whole, according to the instructions that follow. The same procedure applies whether or not the downloaded file contains one or all solvers in SUNDIALS.

The SUNDIALS suite (or individual solvers) are distributed as compressed archives (.tar.gz). The name of the distribution archive is of the form *solver-x.y.z.tar.gz*, where *solver* is one of: sundials, cvode, cvodes, arkode, ida, idas, or kinsol, and x.y.z represents the version number (of the SUNDIALS suite or of the individual solver). To begin the installation, first uncompress and expand the sources, by issuing

% tar xzf solver-x.y.z.tar.gz

This will extract source files under a directory *solver*-x.y.z.

Starting with version 2.6.0 of SUNDIALS, CMake is the only supported method of installation. The explanations of the installation procedure begins with a few common observations:

• The remainder of this chapter will follow these conventions:

solverdir is the directory solver-x.y.z created above; i.e., the directory containing the SUNDI-ALS sources.

builddir is the (temporary) directory under which SUNDIALS is built.

instdir is the directory under which the SUNDIALS exported header files and libraries will be installed. Typically, header files are exported under a directory instdir/include while libraries are installed under instdir/lib, with instdir specified at configuration time.

- For sundials CMake-based installation, in-source builds are prohibited; in other words, the build directory *builddir* can **not** be the same as *solverdir* and such an attempt will lead to an error. This prevents "polluting" the source tree and allows efficient builds for different configurations and/or options.
- The installation directory instdir can **not** be the same as the source directory solverdir.
- By default, only the libraries and header files are exported to the installation directory *instdir*. If enabled by the user (with the appropriate toggle for CMake), the examples distributed with SUNDIALS will be built together with the solver libraries but the installation step will result in exporting (by default in a subdirectory of the installation directory) the example sources and sample outputs together with automatically generated configuration files that reference the *installed* SUNDIALS headers and libraries. As such, these configuration files for the SUNDIALS examples can be used as "templates" for your own problems. CMake installs CMakeLists.txt files and also (as an option available only under Unix/Linux) Makefile files. Note this installation

approach also allows the option of building the SUNDIALS examples without having to install them. (This can be used as a sanity check for the freshly built libraries.)

• Even if generation of shared libraries is enabled, only static libraries are created for the FCMIX modules. (Because of the use of fixed names for the Fortran user-provided subroutines, FCMIX shared libraries would result in "undefined symbol" errors at link time.)

#### A.1 CMake-based installation

CMake-based installation provides a platform-independent build system. CMake can generate Unix and Linux Makefiles, as well as KDevelop, Visual Studio, and (Apple) XCode project files from the same configuration file. In addition, CMake also provides a GUI front end and which allows an interactive build and installation process.

The SUNDIALS build process requires CMake version 3.1.3 or higher and a working C compiler. On Unix-like operating systems, it also requires Make (and curses, including its development libraries, for the GUI front end to CMake, ccmake), while on Windows it requires Visual Studio. CMake is continually adding new features, and the latest version can be downloaded from http://www.cmake.org. Build instructions for CMake (only necessary for Unix-like systems) can be found on the CMake website. Once CMake is installed, Linux/Unix users will be able to use ccmake, while Windows users will be able to use CMakeSetup.

As previously noted, when using CMake to configure, build and install SUNDIALS, it is always required to use a separate build directory. While in-source builds are possible, they are explicitly prohibited by the SUNDIALS CMake scripts (one of the reasons being that, unlike autotools, CMake does not provide a make distclean procedure and it is therefore difficult to clean-up the source tree after an in-source build). By ensuring a separate build directory, it is an easy task for the user to clean-up all traces of the build by simply removing the build directory. CMake does generate a make clean which will remove files generated by the compiler and linker.

#### A.1.1 Configuring, building, and installing on Unix-like systems

The default CMake configuration will build all included solvers and associated examples and will build static and shared libraries. The *installdir* defaults to /usr/local and can be changed by setting the CMAKE\_INSTALL\_PREFIX variable. Support for FORTRAN and all other options are disabled.

CMake can be used from the command line with the cmake command, or from a curses-based GUI by using the ccmake command. Examples for using both methods will be presented. For the examples shown it is assumed that there is a top level SUNDIALS directory with appropriate source, build and install directories:

```
% mkdir (...)sundials/instdir
% mkdir (...)sundials/builddir
% cd (...)sundials/builddir
```

#### Building with the GUI

Using CMake with the GUI follows this general process:

- Select and modify values, run configure (c key)
- New values are denoted with an asterisk
- To set a variable, move the cursor to the variable and press enter
  - If it is a boolean (ON/OFF) it will toggle the value
  - If it is string or file, it will allow editing of the string
  - For file and directories, the <tab> key can be used to complete

- Repeat until all values are set as desired and the generate option is available (g key)
- Some variables (advanced variables) are not visible right away
- To see advanced variables, toggle to advanced mode (t key)
- To search for a variable press / key, and to repeat the search, press the n key

To build the default configuration using the GUI, from the *builddir* enter the ccmake command and point to the *solverdir*:

#### % ccmake ../solverdir

The default configuration screen is shown in Figure A.1.

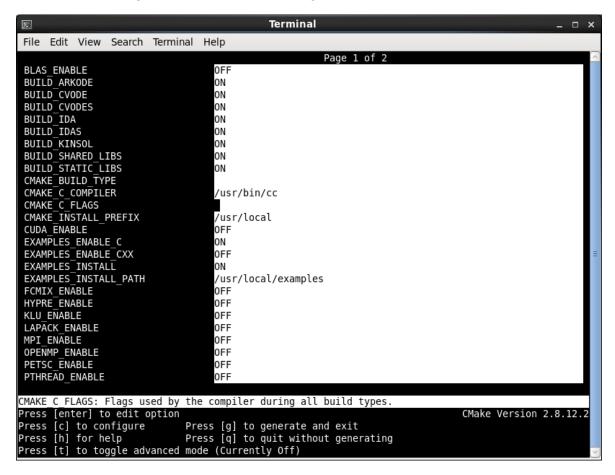

Figure A.1: Default configuration screen. Note: Initial screen is empty. To get this default configuration, press 'c' repeatedly (accepting default values denoted with asterisk) until the 'g' option is available.

The default *instdir* for both SUNDIALS and corresponding examples can be changed by setting the CMAKE\_INSTALL\_PREFIX and the EXAMPLES\_INSTALL\_PATH as shown in figure A.2.

Pressing the (g key) will generate makefiles including all dependencies and all rules to build SUNDIALS on this system. Back at the command prompt, you can now run:

#### % make

To install SUNDIALS in the installation directory specified in the configuration, simply run:

#### % make install

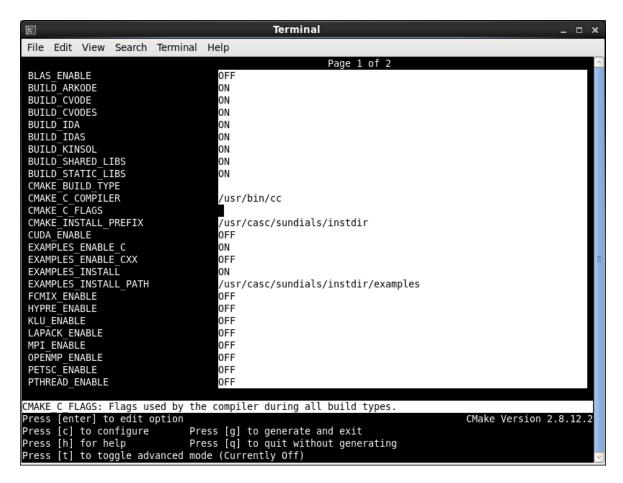

Figure A.2: Changing the *instdir* for SUNDIALS and corresponding examples

#### Building from the command line

Using CMake from the command line is simply a matter of specifying CMake variable settings with the cmake command. The following will build the default configuration:

```
% cmake -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> ../solverdir
% make
% make install
```

### A.1.2 Configuration options (Unix/Linux)

A complete list of all available options for a CMake-based SUNDIALS configuration is provide below. Note that the default values shown are for a typical configuration on a Linux system and are provided as illustration only.

```
BLAS_ENABLE - Enable BLAS support
Default: OFF
```

Note: Setting this option to ON will trigger additional CMake options. See additional information on building with BLAS enabled in A.1.4.

```
BLAS_LIBRARIES - BLAS library
Default: /usr/lib/libblas.so
```

Note: CMake will search for libraries in your LD\_LIBRARY\_PATH prior to searching default system paths.

BUILD\_ARKODE - Build the ARKODE library

Default: ON

BUILD\_CVODE - Build the CVODE library

Default: ON

BUILD\_CVODES - Build the CVODES library

Default: ON

BUILD\_IDA - Build the IDA library

Default: ON

BUILD\_IDAS - Build the IDAS library

Default: ON

BUILD\_KINSOL - Build the KINSOL library

Default: ON

BUILD\_SHARED\_LIBS - Build shared libraries

Default: ON

BUILD\_STATIC\_LIBS - Build static libraries

Default: ON

CMAKE\_BUILD\_TYPE - Choose the type of build, options are: None (CMAKE\_C\_FLAGS used), Debug, Release, RelWithDebInfo, and MinSizeRel

Default:

Note: Specifying a build type will trigger the corresponding build type specific compiler flag options below which will be appended to the flags set by CMAKE\_<language>\_FLAGS.

 ${\tt CMAKE\_C\_COMPILER\ -\ C\ compiler}$ 

Default: /usr/bin/cc

CMAKE\_C\_FLAGS - Flags for C compiler

Default:

CMAKE\_C\_FLAGS\_DEBUG - Flags used by the C compiler during debug builds

Default: -g

CMAKE\_C\_FLAGS\_MINSIZEREL - Flags used by the C compiler during release minsize builds

Default: -Os -DNDEBUG

CMAKE\_C\_FLAGS\_RELEASE - Flags used by the C compiler during release builds

Default: -O3 -DNDEBUG

CMAKE\_CXX\_COMPILER - C++ compiler

Default: /usr/bin/c++

Note: A C++ compiler (and all related options) are only triggered if C++ examples are enabled (EXAMPLES\_ENABLE\_CXX is ON). All SUNDIALS solvers can be used from C++ applications by default without setting any additional configuration options.

CMAKE\_CXX\_FLAGS - Flags for C++ compiler

Default:

 ${\tt CMAKE\_CXX\_FLAGS\_DEBUG~- Flags~used~by~the~C++~compiler~during~debug~builds}$ 

Default: -g

 $\label{eq:cmake_cxx_flags_minsize} \textbf{CMAKE\_CXX\_FLAGS\_MINSIZEREL} \ - \ Flags \ used \ by \ the \ C^{++} \ compiler \ during \ release \ minsize \ builds \\ Default: \ -Os \ -DNDEBUG$ 

 $\label{eq:cmake_cxx_flags_release} \textbf{CMAKE\_CXX\_FLAGS\_RELEASE} \ - \ Flags \ used \ by \ the \ C^{++} \ compiler \ during \ release \ builds \\ Default: \ -O3 \ -DNDEBUG$ 

#### CMAKE\_Fortran\_COMPILER - Fortran compiler

Default: /usr/bin/gfortran

Note: Fortran support (and all related options) are triggered only if either Fortran-C support is enabled (FCMIX\_ENABLE is ON) or BLAS/LAPACK support is enabled (BLAS\_ENABLE or LAPACK\_ENABLE is ON).

#### ${\tt CMAKE\_Fortran\_FLAGS} \ - \ {\tt Flags} \ \ {\tt for} \ \ {\tt Fortran} \ \ {\tt compiler}$

Default:

## CMAKE\_Fortran\_FLAGS\_DEBUG - Flags used by the Fortran compiler during debug builds Default: -g

## CMAKE\_Fortran\_FLAGS\_MINSIZEREL - Flags used by the Fortran compiler during release minsize builds Default: -Os

#### CMAKE\_Fortran\_FLAGS\_RELEASE - Flags used by the Fortran compiler during release builds Default: -O3

#### CMAKE\_INSTALL\_PREFIX - Install path prefix, prepended onto install directories

Default: /usr/local

Note: The user must have write access to the location specified through this option. Exported SUNDIALS header files and libraries will be installed under subdirectories include and lib of CMAKE\_INSTALL\_PREFIX, respectively.

#### CUDA\_ENABLE - Build the SUNDIALS CUDA vector module.

Default: OFF

#### EXAMPLES\_ENABLE\_C - Build the SUNDIALS C examples

Default: ON

#### EXAMPLES\_ENABLE\_CUDA - Build the SUNDIALS CUDA examples

Default: OFF

Note: You need to enable CUDA support to build these examples.

#### EXAMPLES\_ENABLE\_CXX - Build the SUNDIALS C++ examples

Default: OFF

#### EXAMPLES\_ENABLE\_RAJA - Build the SUNDIALS RAJA examples

Default: OFF

Note: You need to enable CUDA and RAJA support to build these examples.

#### EXAMPLES\_ENABLE\_F77 - Build the SUNDIALS Fortran77 examples

Default: ON (if FCMIX\_ENABLE is ON)

#### EXAMPLES\_ENABLE\_F90 - Build the SUNDIALS Fortran90 examples

Default: OFF

#### ${\tt EXAMPLES\_INSTALL~Install~example~files}$

Default: ON

Note: This option is triggered when any of the Sundials example programs are enabled (EXAMPLES\_ENABLE\_<language> is ON). If the user requires installation of example programs then the sources and sample output files for all Sundials modules that are currently enabled will be exported to the directory specified by EXAMPLES\_INSTALL\_PATH. A CMake configuration

script will also be automatically generated and exported to the same directory. Additionally, if the configuration is done under a Unix-like system, makefiles for the compilation of the example programs (using the installed SUNDIALS libraries) will be automatically generated and exported to the directory specified by EXAMPLES\_INSTALL\_PATH.

EXAMPLES\_INSTALL\_PATH - Output directory for installing example files

Default: /usr/local/examples

Note: The actual default value for this option will be an examples subdirectory created under CMAKE\_INSTALL\_PREFIX.

FCMIX\_ENABLE - Enable Fortran-C support

Default: OFF

 ${\tt HYPRE\_ENABLE~-~Enable~} hypre~ {\tt support}$ 

Default: OFF

Note: See additional information on building with hypre enabled in A.1.4.

 ${\tt HYPRE\_INCLUDE\_DIR - Path \ to} \ hypre \ {\tt header \ files}$ 

HYPRE\_LIBRARY\_DIR - Path to hypre installed library files

KLU\_ENABLE - Enable KLU support

Default: OFF

Note: See additional information on building with KLU enabled in A.1.4.

KLU\_INCLUDE\_DIR - Path to SuiteSparse header files

KLU\_LIBRARY\_DIR - Path to SuiteSparse installed library files

LAPACK\_ENABLE - Enable LAPACK support

Default: OFF

Note: Setting this option to ON will trigger additional CMake options. See additional information on building with LAPACK enabled in A.1.4.

LAPACK\_LIBRARIES - LAPACK (and BLAS) libraries

Default: /usr/lib/liblapack.so;/usr/lib/libblas.so

Note: CMake will search for libraries in your LD\_LIBRARY\_PATH prior to searching default system paths.

MPI\_ENABLE - Enable MPI support (build the parallel nvector).

Default: OFF

Note: Setting this option to ON will trigger several additional options related to MPI.

MPI\_C\_COMPILER - mpicc program

Default:

MPI\_CXX\_COMPILER - mpicxx program

Default:

Note: This option is triggered only if MPI is enabled (MPI\_ENABLE is ON) and C++ examples are enabled (EXAMPLES\_ENABLE\_CXX is ON). All SUNDIALS solvers can be used from C++ MPI applications by default without setting any additional configuration options other than MPI\_ENABLE.

MPI\_Fortran\_COMPILER - mpif77 or mpif90 program

Default:

Note: This option is triggered only if MPI is enabled (MPI\_ENABLE is ON), Fortran-C support is enabled (FCMIX\_ENABLE is ON), and Fortran77 or Fortran90 examples are enabled (EXAMPLES\_ENABLE\_F77 or EXAMPLES\_ENABLE\_F90 are ON).

MPIEXEC\_EXECUTABLE - Specify the executable for running MPI programs

Default: mpirun

Note: This option is triggered only if MPI is enabled (MPI\_ENABLE is ON).

OPENMP\_ENABLE - Enable OpenMP support (build the OpenMP nvector).

Default: OFF

PETSC\_ENABLE - Enable PETSc support

Default: OFF

Note: See additional information on building with PETSc enabled in A.1.4.

PETSC\_INCLUDE\_DIR - Path to PETSc header files

PETSC\_LIBRARY\_DIR - Path to PETSc installed library files

PTHREAD\_ENABLE - Enable Pthreads support (build the Pthreads nvector).

Default: OFF

RAJA\_ENABLE - Enable RAJA support (build the RAJA nvector).

Default: OFF

Note: You need to enable CUDA in order to build the RAJA vector module.

SUNDIALS\_F77\_FUNC\_CASE - advanced option - Specify the case to use in the Fortran name-mangling scheme, options are: lower or upper

Default:

Note: The build system will attempt to infer the Fortran name-mangling scheme using the Fortran compiler. This option should only be used if a Fortran compiler is not available or to override the inferred or default (lower) scheme if one can not be determined. If used, SUNDIALS\_F77\_FUNC\_UNDERSCORES must also be set.

SUNDIALS\_F77\_FUNC\_UNDERSCORES - advanced option - Specify the number of underscores to append in the Fortran name-mangling scheme, options are: none, one, or two Default:

Note: The build system will attempt to infer the Fortran name-mangling scheme using the Fortran compiler. This option should only be used if a Fortran compiler is not available or to override the inferred or default (one) scheme if one can not be determined. If used, SUNDIALS\_F77\_FUNC\_CASE must also be set.

#### SUNDIALS\_INDEX\_TYPE - advanced

Integer type used for SUNDIALS indices. The size must match the size provided for the SUNDIALS\_INDEX\_SIZE option.

Default:

Note: In past SUNDIALS versions, a user could set this option to INT64\_T to use 64-bit integers, or INT32\_T to use 32-bit integers. Starting in SUNDIALS 3.2.0, these special values are deprecated. For SUNDIALS 3.2.0 and up, a user will only need to use the SUNDIALS\_INDEX\_SIZE option in most cases.

SUNDIALS\_INDEX\_SIZE - Integer size (in bits) used for indices in SUNDIALS, options are: 32 or 64 Default: 64

Note: The build system tries to find an integer type of appropriate size. Candidate 64-bit integer types are (in order of preference): int64\_t, \_\_int64, long long, and long. Candidate 32-bit integers are (in order of preference): int32\_t, int, and long. The advanced option, SUNDIALS\_INDEX\_TYPE can be used to provide a type not listed here.

SUNDIALS\_PRECISION - Precision used in SUNDIALS, options are: double, single, or extended Default: double

SUPERLUMT\_ENABLE - Enable SuperLU\_MT support

Default: OFF

Note: See additional information on building with SuperLU\_MT enabled in A.1.4.

SUPERLUMT\_INCLUDE\_DIR - Path to SuperLU\_MT header files (typically SRC directory)

SUPERLUMT\_LIBRARY\_DIR - Path to SuperLU\_MT installed library files

SUPERLUMT\_THREAD\_TYPE - Must be set to Pthread or OpenMP

Default: Pthread

USE\_GENERIC\_MATH - Use generic (stdc) math libraries

Default: ON

#### **xSDK** Configuration Options

SUNDIALS supports CMake configuration options defined by the Extreme-scale Scientific Software Development Kit (xSDK) community policies (see https://xsdk.info for more information). xSDK CMake options are unused by default but may be activated by setting USE\_XSDK\_DEFAULTS to ON.

When xSDK options are active, they will overwrite the corresponding SUNDIALS option and may have different default values (see details below). As such the equivalent SUNDIALS options should not be used when configuring with xSDK options. In the GUI front end to CMake (ccmake), setting USE\_XSDK\_DEFAULTS to ON will hide the corresponding SUNDIALS options as advanced CMake variables. During configuration, messages are output detailing which xSDK flags are active and the equivalent SUNDIALS options that are replaced. Below is a complete list xSDK options and the corresponding SUNDIALS options if applicable.

#### TPL\_BLAS\_LIBRARIES - BLAS library

Default: /usr/lib/libblas.so

SUNDIALS equivalent: BLAS\_LIBRARIES

Note: CMake will search for libraries in your  ${\tt LD\_LIBRARY\_PATH}$  prior to searching default system

paths.

TPL\_ENABLE\_BLAS - Enable BLAS support

Default: OFF

SUNDIALS equivalent: BLAS\_ENABLE

TPL\_ENABLE\_HYPRE - Enable hypre support

Default: OFF

SUNDIALS equivalent: HYPRE\_ENABLE

TPL\_ENABLE\_KLU - Enable KLU support

Default: OFF

SUNDIALS equivalent: KLU\_ENABLE

TPL\_ENABLE\_PETSC - Enable PETSc support

Default: OFF

SUNDIALS equivalent: PETSC\_ENABLE

TPL\_ENABLE\_LAPACK - Enable LAPACK support

Default: OFF

SUNDIALS equivalent: LAPACK\_ENABLE

TPL\_ENABLE\_SUPERLUMT - Enable SuperLU\_MT support

Default: OFF

SUNDIALS equivalent: SUPERLUMT\_ENABLE

 $\mathtt{TPL\_HYPRE\_INCLUDE\_DIRS}$  - Path to hypre header files

SUNDIALS equivalent: HYPRE\_INCLUDE\_DIR

### ${\tt TPL\_HYPRE\_LIBRARIES} \ - \ hypre \ {\tt library}$

SUNDIALS equivalent: N/A

#### TPL\_KLU\_INCLUDE\_DIRS - Path to KLU header files

SUNDIALS equivalent: KLU\_INCLUDE\_DIR

#### TPL\_KLU\_LIBRARIES - KLU library

SUNDIALS equivalent: N/A

#### TPL\_LAPACK\_LIBRARIES - LAPACK (and BLAS) libraries

Default: /usr/lib/liblapack.so;/usr/lib/libblas.so

SUNDIALS equivalent: LAPACK\_LIBRARIES

Note: CMake will search for libraries in your LD\_LIBRARY\_PATH prior to searching default system

paths.

#### TPL\_PETSC\_INCLUDE\_DIRS - Path to PETSc header files

SUNDIALS equivalent: PETSC\_INCLUDE\_DIR

### TPL\_PETSC\_LIBRARIES - PETSc library

SUNDIALS equivalent: N/A

#### TPL\_SUPERLUMT\_INCLUDE\_DIRS - Path to SuperLU\_MT header files

SUNDIALS equivalent: SUPERLUMT\_INCLUDE\_DIR

#### TPL\_SUPERLUMT\_LIBRARIES - SuperLU\_MT library

SUNDIALS equivalent: N/A

#### TPL\_SUPERLUMT\_THREAD\_TYPE - SuperLU\_MT library thread type

SUNDIALS equivalent: SUPERLUMT\_THREAD\_TYPE

#### USE\_XSDK\_DEFAULTS - Enable xSDK default configuration settings

Default: OFF

SUNDIALS equivalent: N/A

Note: Enabling xSDK defaults also sets CMAKE\_BUILD\_TYPE to Debug

#### XSDK\_ENABLE\_FORTRAN - Enable SUNDIALS Fortran interface

Default: OFF

SUNDIALS equivalent: FCMIX\_ENABLE

#### XSDK\_INDEX\_SIZE - Integer size (bits) used for indices in SUNDIALS, options are: 32 or 64

Default: 32

SUNDIALS equivalent: SUNDIALS\_INDEX\_SIZE

#### XSDK\_PRECISION - Precision used in SUNDIALS, options are: double, single, or quad

Default: double

SUNDIALS equivalent: SUNDIALS\_PRECISION

#### A.1.3 Configuration examples

The following examples will help demonstrate usage of the CMake configure options.

To configure SUNDIALS using the default C and Fortran compilers, and default mpic and mpif77 parallel compilers, enable compilation of examples, and install libraries, headers, and example sources under subdirectories of /home/myname/sundials/, use:

#### % cmake \

- > -DCMAKE\_INSTALL\_PREFIX=/home/myname/sundials/instdir \
- > -DEXAMPLES\_INSTALL\_PATH=/home/myname/sundials/instdir/examples \
- > -DMPI\_ENABLE=ON \
- > -DFCMIX\_ENABLE=ON \

```
> /home/myname/sundials/solverdir
%
% make install
%
```

To disable installation of the examples, use:

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DMPI_ENABLE=ON \
> -DFCMIX_ENABLE=ON \
> -DEXAMPLES_INSTALL=OFF \
> /home/myname/sundials/solverdir
%
% make install
%
```

### A.1.4 Working with external Libraries

The SUNDIALS suite contains many options to enable implementation flexibility when developing solutions. The following are some notes addressing specific configurations when using the supported third party libraries. When building SUNDIALS as a shared library external libraries any used with SUNDIALS must also be build as a shared library or as a static library compiled with the -fPIC flag.

### ⚠

#### Building with BLAS

SUNDIALS does not utilize BLAS directly but it may be needed by other external libraries that SUNDIALS can be built with (e.g. LAPACK, PETSc, SuperLU\_MT, etc.). To enable BLAS, set the BLAS\_ENABLE option to ON. If the directory containing the BLAS library is in the LD\_LIBRARY\_PATH environment variable, CMake will set the BLAS\_LIBRARIES variable accordingly, otherwise CMake will attempt to find the BLAS library in standard system locations. To explicitly tell CMake what libraries to use, the BLAS\_LIBRARIES variable can be set to the desired library. Example:

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DBLAS_ENABLE=ON \
> -DBLAS_LIBRARIES=/myblaspath/lib/libblas.so \
> -DSUPERLUMT_ENABLE=ON \
> -DSUPERLUMT_INCLUDE_DIR=/mysuperlumtpath/SRC
> -DSUPERLUMT_LIBRARY_DIR=/mysuperlumtpath/lib
> /home/myname/sundials/solverdir
%
% make install
%
```

When allowing CMake to automatically locate the LAPACK library, CMake may also locate the corresponding BLAS library.

If a working Fortran compiler is not available to infer the Fortran name-mangling scheme, the options SUNDIALS\_F77\_FUNC\_CASE and SUNDIALS\_F77\_FUNC\_UNDERSCORES must be set in order to bypass the check for a Fortran compiler and define the name-mangling scheme. The defaults for these options in earlier versions of SUNDIALS were lower and one respectively.

#### **Building with LAPACK**

> /home/myname/sundials/solverdir

To enable LAPACK, set the LAPACK\_ENABLE option to ON. If the directory containing the LAPACK library is in the LD\_LIBRARY\_PATH environment variable, CMake will set the LAPACK\_LIBRARIES variable accordingly, otherwise CMake will attempt to find the LAPACK library in standard system locations. To explicitly tell CMake what library to use, the LAPACK\_LIBRARIES variable can be set to the desired libraries. When setting the LAPACK location explicitly the location of the corresponding BLAS library will also need to be set. Example:

```
% cmake \
> -DCMAKE_INSTALL_PREFIX=/home/myname/sundials/instdir \
> -DEXAMPLES_INSTALL_PATH=/home/myname/sundials/instdir/examples \
> -DBLAS_ENABLE=ON \
> -DBLAS_LIBRARIES=/mylapackpath/lib/libblas.so \
> -DLAPACK_ENABLE=ON \
> -DLAPACK_LIBRARIES=/mylapackpath/lib/liblapack.so \
```

When allowing CMake to automatically locate the LAPACK library, CMake may also locate the corresponding BLAS library.

If a working Fortran compiler is not available to infer the Fortran name-mangling scheme, the options SUNDIALS\_F77\_FUNC\_CASE and SUNDIALS\_F77\_FUNC\_UNDERSCORES must be set in order to bypass the check for a Fortran compiler and define the name-mangling scheme. The defaults for these options in earlier versions of SUNDIALS were lower and one respectively.

#### Building with KLU

% make install

The KLU libraries are part of SuiteSparse, a suite of sparse matrix software, available from the Texas A&M University website: http://faculty.cse.tamu.edu/davis/suitesparse.html. SUNDIALS has been tested with SuiteSparse version 4.5.3. To enable KLU, set KLU\_ENABLE to ON, set KLU\_INCLUDE\_DIR to the include path of the KLU installation and set KLU\_LIBRARY\_DIR to the lib path of the KLU installation. The CMake configure will result in populating the following variables: AMD\_LIBRARY, AMD\_LIBRARY\_DIR, BTF\_LIBRARY\_DIR, COLAMD\_LIBRARY, COLAMD\_LIBRARY\_DIR, and KLU\_LIBRARY.

#### Building with SuperLU\_MT

The SuperLU\_MT libraries are available for download from the Lawrence Berkeley National Laboratory website: http://crd-legacy.lbl.gov/~xiaoye/SuperLU/#superlu\_mt. SUNDIALS has been tested with SuperLU\_MT version 3.1. To enable SuperLU\_MT, set SUPERLUMT\_ENABLE to ON, set SUPERLUMT\_INCLUDE\_DIR to the SRC path of the SuperLU\_MT installation, and set the variable SUPERLUMT\_LIBRARY\_DIR to the lib path of the SuperLU\_MT installation. At the same time, the variable SUPERLUMT\_THREAD\_TYPE must be set to either Pthread or OpenMP.

Do not mix thread types when building SUNDIALS solvers. If threading is enabled for SUNDIALS by having either OPENMP\_ENABLE or PTHREAD\_ENABLE set to ON then SuperLU\_MT should be set to use the same threading type.

#### Building with PETSc

The PETSc libraries are available for download from the Argonne National Laboratory website: http://www.mcs.anl.gov/petsc. SUNDIALS has been tested with PETSc version 3.7.2. To enable PETSc, set PETSC\_ENABLE to ON, set PETSC\_INCLUDE\_DIR to the include path of the PETSc installation, and set the variable PETSC\_LIBRARY\_DIR to the lib path of the PETSc installation.

#### Building with hypre

The hypre libraries are available for download from the Lawrence Livermore National Laboratory website: http://computation.llnl.gov/projects/hypre. SUNDIALS has been tested with hypre version 2.11.1. To enable hypre, set HYPRE\_ENABLE to ON, set HYPRE\_INCLUDE\_DIR to the include path of the hypre installation, and set the variable HYPRE\_LIBRARY\_DIR to the lib path of the hypre installation.

#### Building with CUDA

SUNDIALS CUDA modules and examples have been tested with version 8.0 of the CUDA toolkit. To build them, you need to install the Toolkit and compatible NVIDIA drivers. Both are available for download from the NVIDIA website: https://developer.nvidia.com/cuda-downloads. To enable CUDA, set CUDA\_ENABLE to ON. If CUDA is installed in a nonstandard location, you may be prompted to set the variable CUDA\_TOOLKIT\_ROOT\_DIR with your CUDA Toolkit installation path. To enable CUDA examples, set EXAMPLES\_ENABLE\_CUDA to ON.

#### Building with RAJA

RAJA is a performance portability layer developed by Lawrence Livermore National Laboratory and can be obtained from https://github.com/LLNL/RAJA. SUNDIALS RAJA modules and examples have been tested with RAJA version 0.3. Building SUNDIALS RAJA modules requires a CUDA-enabled RAJA installation. To enable RAJA, set CUDA\_ENABLE and RAJA\_ENABLE to ON. If RAJA is installed in a nonstandard location you will be prompted to set the variable RAJA\_DIR with the path to the RAJA CMake configuration file. To enable building the RAJA examples set EXAMPLES\_ENABLE\_RAJA to ON.

#### A.1.5 Testing the build and installation

If SUNDIALS was configured with EXAMPLES\_ENABLE\_<language> options to ON, then a set of regression tests can be run after building with the make command by running:

% make test

Additionally, if EXAMPLES\_INSTALL was also set to ON, then a set of smoke tests can be run after installing with the make install command by running:

% make test\_install

### A.2 Building and Running Examples

Each of the SUNDIALS solvers is distributed with a set of examples demonstrating basic usage. To build and install the examples, set at least of the EXAMPLES\_ENABLE\_<language> options to ON, and set EXAMPLES\_INSTALL to ON. Specify the installation path for the examples with the variable EXAMPLES\_INSTALL\_PATH. CMake will generate CMakeLists.txt configuration files (and Makefile files if on Linux/Unix) that reference the *installed* SUNDIALS headers and libraries.

Either the CMakeLists.txt file or the traditional Makefile may be used to build the examples as well as serve as a template for creating user developed solutions. To use the supplied Makefile simply run make to compile and generate the executables. To use CMake from within the installed example directory, run cmake (or ccmake to use the GUI) followed by make to compile the example code. Note that if CMake is used, it will overwrite the traditional Makefile with a new CMake-generated Makefile. The resulting output from running the examples can be compared with example output bundled in the SUNDIALS distribution.

NOTE: There will potentially be differences in the output due to machine architecture, compiler versions, use of third party libraries etc.

#### **A.3** Configuring, building, and installing on Windows

CMake can also be used to build SUNDIALS on Windows. To build SUNDIALS for use with Visual Studio the following steps should be performed:

- 1. Unzip the downloaded tar file(s) into a directory. This will be the solverdir
- 2. Create a separate builddir
- 3. Open a Visual Studio Command Prompt and cd to builddir
- 4. Run cmake-gui ../solverdir
  - (a) Hit Configure
  - (b) Check/Uncheck solvers to be built
  - (c) Change CMAKE\_INSTALL\_PREFIX to instdir
  - (d) Set other options as desired
  - (e) Hit Generate
- 5. Back in the VS Command Window:
  - (a) Run msbuild ALL\_BUILD.vcxproj
  - (b) Run msbuild INSTALL.vcxproj

The resulting libraries will be in the *instdir*. The SUNDIALS project can also now be opened in Visual Studio. Double click on the ALL\_BUILD.vcxproj file to open the project. Build the whole solution to create the SUNDIALS libraries. To use the SUNDIALS libraries in your own projects, you must set the include directories for your project, add the SUNDIALS libraries to your project solution, and set the SUNDIALS libraries as dependencies for your project.

#### $\mathbf{A.4}$ Installed libraries and exported header files

Using the CMake SUNDIALS build system, the command

% make install

will install the libraries under libdir and the public header files under includedir. The values for these directories are instdir/lib and instdir/include, respectively. The location can be changed by setting the CMake variable CMAKE\_INSTALL\_PREFIX. Although all installed libraries reside under libdir/lib, the public header files are further organized into subdirectories under includedir/include.

The installed libraries and exported header files are listed for reference in Table A.1. The file extension .lib is typically .so for shared libraries and .a for static libraries. Note that, in the Tables, names are relative to *libdir* for libraries and to *includedir* for header files.

A typical user program need not explicitly include any of the shared SUNDIALS header files from under the includedir/include/sundials directory since they are explicitly included by the appropriate solver header files (e.g., cvode\_dense.h includes sundials\_dense.h). However, it is both legal and safe to do so, and would be useful, for example, if the functions declared in sundials\_dense.h are to be used in building a preconditioner.

Table A 1. GINDLAIG libraries and bandon floo

## Appendix B

# **CVODES** Constants

Below we list all input and output constants used by the main solver and linear solver modules, together with their numerical values and a short description of their meaning.

### **B.1** CVODES input constants

	CV	ODES main solver module
CV_ADAMS	1	Adams-Moulton linear multistep method.
CV_BDF	2	BDF linear multistep method.
CV_FUNCTIONAL	1	Nonlinear system solution through functional iterations.
CV_NEWTON	2	Nonlinear system solution through Newton iterations.
CV_NORMAL	1	Solver returns at specified output time.
CV_ONE_STEP	2	Solver returns after each successful step.
CV_SIMULTANEOUS	1	Simultaneous corrector forward sensitivity method.
CV_STAGGERED	2	Staggered corrector forward sensitivity method.
CV_STAGGERED1	3	Staggered (variant) corrector forward sensitivity method.
CV_CENTERED	1	Central difference quotient approximation $(2^{nd} \text{ order})$ of the sensitivity RHS.
CV_FORWARD	2	Forward difference quotient approximation $(1^{st} \text{ order})$ of the sensitivity RHS.
	CVC	DDES adjoint solver module
CV_HERMITE	1	Use Hermite interpolation.
CV_POLYNOMIAL	2	Use variable-degree polynomial interpolation.
	Iter	rative linear solver module
PREC NONE	0	No preconditioning
	_	-
	_	· ·
CV_HERMITE	1 2	Forward difference quotient approximation (1s sensitivity RHS.  DDES adjoint solver module  Use Hermite interpolation.  Use variable-degree polynomial interpolation.

260 CVODES Constants

PREC_BOTH	3	Preconditioning on both the left and the right.
MODIFIED_GS	1	Use modified Gram-Schmidt procedure.
${\tt CLASSICAL\_GS}$	2	Use classical Gram-Schmidt procedure.

### B.2 CVODES output constants

	CVO	ODES main solver module
CV_SUCCESS	0	Successful function return.
CV_SOCCESS CV_TSTOP_RETURN	1	CVode succeeded by reaching the specified stopping point.
CV_ROOT_RETURN	2	CVode succeeded and found one or more roots.
CV_WARNING	99	CVode succeeded but an unusual situation occurred.
CV_WARRING CV_TOO_MUCH_WORK	-1	The solver took mxstep internal steps but could not reach tout.
CV_TOO_MUCH_ACC	-2	The solver could not satisfy the accuracy demanded by the user for some internal step.
CV_ERR_FAILURE	-3	Error test failures occurred too many times during one internal time step or minimum step size was reached.
CV_CONV_FAILURE	-4	Convergence test failures occurred too many times during one internal time step or minimum step size was reached.
CV_LINIT_FAIL	-5	The linear solver's initialization function failed.
CV_LSETUP_FAIL	-6	The linear solver's setup function failed in an unrecoverable manner.
CV_LSOLVE_FAIL	-7	The linear solver's solve function failed in an unrecoverable manner.
CV_RHSFUNC_FAIL	-8	The right-hand side function failed in an unrecoverable manner.
CV_FIRST_RHSFUNC_ERR	-9	The right-hand side function failed at the first call.
CV_REPTD_RHSFUNC_ERR	-10	The right-hand side function had repetead recoverable errors.
CV_UNREC_RHSFUNC_ERR	-11	The right-hand side function had a recoverable error, but no recovery is possible.
CV_RTFUNC_FAIL	-12	The rootfinding function failed in an unrecoverable manner.
CV_CONSTR_FAIL	-13	The inequality constraints were violated and the solver was unable to recover.
CV_MEM_FAIL	-20	A memory allocation failed.
CV_MEM_NULL	-21	The cvode_mem argument was NULL.
CV_ILL_INPUT	-22	One of the function inputs is illegal.
CV_NO_MALLOC	-23	The CVODE memory block was not allocated by a call to CVodeMalloc.
CV_BAD_K	-24	The derivative order $k$ is larger than the order used.
CV_BAD_T	-25	The time $t$ is outside the last step taken.
CV_BAD_DKY	-26	The output derivative vector is NULL.
CV_TOO_CLOSE	-27	The output and initial times are too close to each other.
CV_NO_QUAD	-30	Quadrature integration was not activated.

CV_QRHSFUNC_FAIL	-31	The quadrature right-hand side function failed in an unrecoverable manner.
CV_FIRST_QRHSFUNC_ERR	-32	The quadrature right-hand side function failed at the first call.
CV_REPTD_QRHSFUNC_ERR	-33	The quadrature ight-hand side function had repetead recov-
CV_UNREC_QRHSFUNC_ERR	-34	erable errors.  The quadrature right-hand side function had a recoverable
GV NO GENG	40	error, but no recovery is possible.
CV_NO_SENS	-40	Forward sensitivity integration was not activated.
CV_SRHSFUNC_FAIL	-41	The sensitivity right-hand side function failed in an unre-
	40	coverable manner.
CV_FIRST_SRHSFUNC_ERR	-42	The sensitivity right-hand side function failed at the first call.
CV_REPTD_SRHSFUNC_ERR	-43	The sensitivity ight-hand side function had repeted recov-
CV_REF ID_SIMISFONC_EIM	-40	erable errors.
CV_UNREC_SRHSFUNC_ERR	-44	The sensitivity right-hand side function had a recoverable
CV_UNREC_SRESFUNC_ERR	-44	* •
ON DAD TO	45	error, but no recovery is possible.
CV_BAD_IS	-45	The sensitivity index is larger than the number of sensitivi-
a a a		ties computed.
CV_NO_QUADSENS	-50	Forward sensitivity integration was not activated.
CV_QSRHSFUNC_FAIL	-51	The sensitivity right-hand side function failed in an unre-
		coverable manner.
CV_FIRST_QSRHSFUNC_ERR	-52	The sensitivity right-hand side function failed at the first call.
CV_REPTD_QSRHSFUNC_ERR	-53	The sensitivity ight-hand side function had repeted recov-
OV Ith ID Worthol ONO Little	-00	erable errors.
CV_UNREC_QSRHSFUNC_ERR	-54	The sensitivity right-hand side function had a recoverable
CV_ONITEC_dentities. ONG_Entit	-94	error, but no recovery is possible.
		circly but no receivery is possible.
	CVOI	DES adjoint solver module
CV_NO_ADJ	-101	Adjoint module was not initialized.
CV_NO_FWD	-102	The forward integration was not yet performed.
CV_NO_BCK	-103	No backward problem was specified.
CV_BAD_TB0	-104	The final time for the adjoint problem is outside the interval
		over which the forward problem was solved.
CV_REIFWD_FAIL	-105	Reinitialization of the forward problem failed at the first
		checkpoint.
CV_FWD_FAIL	-106	An error occurred during the integration of the forward
	-00	problem.
CV_GETY_BADT	-107	Wrong time in interpolation function.
	-0.	
	CVI	OLS linear solver modules
	_	
CVDLS_SUCCESS	0	Successful function return.
CVDLS_MEM_NULL	-1	The cvode_mem argument was NULL.
CVDLS_LMEM_NULL	-2	The CVDLS linear solver has not been initialized.

262 CVODES Constants

CVDLS_ILL_INPUT	-3	The CVDLs solver is not compatible with the current NVEC-
CUDI C MEM EAT	4	TOR module.
CVDLS_MEM_FAIL	-4	A memory allocation request failed.
CVDLS_JACFUNC_UNRECVR	-5	The Jacobian function failed in an unrecoverable manner.
CVDLS_JACFUNC_RECVR	-6	The Jacobian function had a recoverable error.
CVDLS_SUNMAT_FAIL	-7	An error occurred with the current SUNMATRIX module.
CVDLS_NO_ADJ	-101	The combined forward-backward problem has not been ini-
		tialized.
CVDLS_LMEMB_NULL	-102	The linear solver was not initialized for the backward phase.
	CVE	DIAG linear solver module
CVDIAG_SUCCESS	0	Successful function return.
CVDIAG_MEM_NULL	-1	The cvode_mem argument was NULL.
CVDIAG_LMEM_NULL	-2	The CVDIAG linear solver has not been initialized.
CVDIAG_ILL_INPUT	-3	The CVDIAG solver is not compatible with the current NVEC-
		TOR module.
CVDIAG_MEM_FAIL	-4	A memory allocation request failed.
CVDIAG_INV_FAIL	-5	A diagonal element of the Jacobian was 0.
CVDIAG_RHSFUNC_UNRECVR	-6	The right-hand side function failed in an unrecoverable man-
		ner.
CVDIAG_RHSFUNC_RECVR	-7	The right-hand side function had a recoverable error.
CVDIAG_NO_ADJ	-101	The combined forward-backward problem has not been ini-
		tialized.
	CVSI	PILS linear solver modules
	0 1 51	incui sorver modules
CVSPILS_SUCCESS	0	Successful function return.
CVSPILS_MEM_NULL	-1	The cvode_mem argument was NULL.
CVSPILS_LMEM_NULL	-2	The CVSPILS linear solver has not been initialized.
CVSPILS_ILL_INPUT	-3	The CVSPILS solver is not compatible with the current NVEC-
		TOR module, or an input value was illegal.
CVSPILS_MEM_FAIL	-4	A memory allocation request failed.
CVSPILS_PMEM_NULL	-5	The preconditioner module has not been initialized.
CVSPILS_SUNLS_FAIL	-6	An error occurred with the current SUNLINSOL module.
CVSPILS_NO_ADJ	-101	The combined forward-backward problem has not been ini-
		tialized.
CVSPILS_LMEMB_NULL	-102	The linear solver was not initialized for the backward phase.
